Compositions and Methods for Polynucleotide Delivery

Description

Field of the Invention

This invention relates to compositions and methods for increasing the uptake of polynucleotides into cells. Specifically, the invention relates to vectors, targeting ligands, and polycationic agents. The polycationic agents are capable of (1) increasing the frequency of uptake of polynucleotides into a cell, (2) condensing polynucleotides; and (3) inhibiting serum and/or nuclease degradation of polynucleotides.

10 Background of the Invention

Polycations, such as polylysine, have been used to facilitate delivery of nucleic acids to cell interior. Both *in vitro* and *in vivo* applications have taken advantage of this property. See, for example, Gao *et al.*, 1996, *Biochem.* 35:1027-1036.

15 Polynucleotides, typically DNA, may be taken into a cell by a receptor-mediated endocytosis pathway, a cellular mechanism which internalizes specific macromolecules. In general, complexes designed to be delivered in this fashion contain nucleic acids encoding the gene of interest and a polycationic agent, which acts as a DNA-binding carrier and both neutralizes the charge on the
20 nucleic acids and condenses it.

Condensation facilitates entry of nucleic acids into cell vesicle systems by simulating a macromolecular structure. For example, polylysine condenses DNA into a toroid or doughnut-like structure. (Wagner *et al.*, 1991, *Proc. Natl. Acad. Sci.* 88:4255-4259).

25 Polycations previously utilized for nucleic acid delivery to cell interiors include polylysine, protamines, histones, spermine, spermidine, polyornithine, polyarginine, and putrescine.

All publications mentioned herein are incorporated herein by reference for the purpose of disclosing and describing features of the invention for which
30 the publications are cited in connection with.

Summary of the Invention

An embodiment of the invention is a vector for expression of polypeptides. The vector of the instant invention comprises: (i) an Epstein Barr Virus (EBV) origin of replication; (ii) a polynucleotide encoding an EBV origin binding protein; (iii) an enhancer; (iv) a promoter; and (v) a terminator.

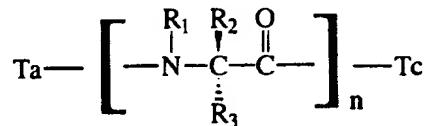

Polynucleotides encoding a desired polypeptide, such as erythropoietin or leptin can be inserted into the vector. Also, ribozyme and antisense polynucleotides can also be inserted into the vector.

One embodiment of the invention is a composition capable of targeting a polynucleotide to a specific cell type. The composition comprises: (i) a lipoprotein; (ii) a polynucleotide binding molecule; and (iii) a polynucleotide.

Another embodiment of the invention is a method of increasing the frequency of uptake of polynucleotides into a cell by contacting a cell with a composition comprising: (i) a lipoprotein, (ii) a polynucleotide binding molecule; and (iii) a polynucleotide.

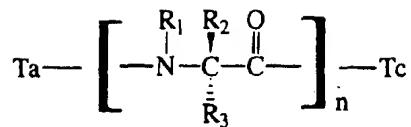

Yet another embodiment of the invention is a method of increasing the frequency of uptake of polynucleotides into a specific cell type by contacting a population of cells with a composition comprising (i) a lipoprotein, (ii) a polynucleotide binding molecule; and (iii) a polynucleotide.

One embodiment of the invention is a polycationic agent exhibiting a net positive electrical charge at physiological pH with the following formula:

where Ta and Tc are terminating groups. A preferred subset of these compounds is the set where R₂ is hydrogen. Even more preferred are polymers comprising at least one unnatural amino acid. Also preferred are polymers where R₁ and R₃ are hydrogen and R₂ is not hydrogen, also referred to as poly N-substituted glycines or "poly NSGs."

Another embodiment is a neutral polymer exhibiting no net positive or negative electrical charge at physiological pH with the following formula:

where Ta and Tc are terminating groups. A preferred subset of these compounds is the set where R₁ is hydrogen. Even more preferred are polymers comprising at least one unnatural amino acid. Also preferred are polymers where R₂ and R₃ are hydrogen and R₁ is not hydrogen, also referred to as poly N-substituted glycines or "poly NSGs."

The instant polycationic agents and neutral polymers are capable of neutralizing the electrical charge of nucleic acids. A subset of these compounds are capable of (1) condensing the structure of polynucleotides and/ or (2) protecting polynucleotides from serum and/or nuclease degradation.

10 Yet another embodiment of the invention are polycationic agents and neutral polymers that (1) target binding of nucleic acids to cell surfaces, (2) trigger cell membrane destabilization; (3) exhibit endosome buffering capacity (4) trigger endocytosis; (5) help trigger the release of polynucleotide/lipid complexes from endosomes or (6) nuclear tropism.

15 Another embodiment of the invention is a composition comprising a
polynucleotide of interest and an effective amount of the polycationic agent to
neutralize the charge of the polynucleotide. Optionally, the composition includes
a ligand which directs the complex to particular cells expressing a ligand-binding
partner, and/or an endosomolytic agent, which serves to cause disruption of the
endosome containing the complex.
20

Another embodiment of the invention is a method of condensing nucleic acids by providing an effective amount of the polycationic agents or neutral polymers of the invention and contacting the agent with the desired polynucleotides.

25 Also an embodiment of the invention is a method of inhibiting serum
and/or nuclease degradation of nucleic acids by providing an effective amount of
the the polycationic agents or neutral polymers of the inventions and contacting
the agent with the desired nucleic acids.

Brief Description of the Drawings

Figure 1 is a schematic of a two-step monomer assembly reaction scheme.

5 Figure 2 is a schematic of a three-step monomer assembly reaction scheme.

Figure 3 is a plasmid map of vector pCMVKmITR-EPI.

Figure 4 is a plasmid map of vector CMVkm2.

Figure 5 is a plasmid map of vector pCMV-KM-cmEPO.

Figure 6 is a plasmid map of vector CMVKmLeptinWt.

10 Figure 7A illustrates transfection efficiencies for a diverse set of polycationic agents. The polycatonic agents were formulated with DNA at a 2:1, + to - charge ratio and added to either HT1080 (solid bar) or COS (stippled bar) in the presence of 10% serum. Luciferase activity was analyzed 48 hours post-transfection. Total cell protein was measured using a Pierce BCA assay and 15 luciferase activity was normalized against total cell protein.

Figure 7B illustrates the effect of oligomer length on transfection efficiency for polycationic agents having different numbers of the same repeating trimer motif. For both A and B each data point represents the average of 2 experiments.

20 Figure 8(A-C) shows RZ145-1 peptoid-mediated transfection and transfection mediated by commercially available cationic liposome preparations. RZ145-1 or the indicated lipid was formulated and added to cells in the presence (solid bar) or absence (stippled bar) of 10% serum. Luciferase and total cell protein activity were measured 48 hours after initial transfection. Cells lines are 25 (Figure 8A) 293 human embryonic kidney cells, (Figure 8B) HT1080 human fibrosarcoma cells, and (Figure 8C) NIH03T3 mouse fibroblast cells. Each data point represents the average + standard error of the mean of three transfections.

Figure 9 illustrates the effect of chloroquine on transfection with RZ145-1 in (A) 293 cells and (B) HT1080 cells. The cells were transfected in the 30 presence (black bar) or absence (stippled bar) of 100 uM chloroquine. Cells were lysed 48 hours post transfection and luciferase activity and total protein content were measured.

Detailed DescriptionDefinitions

"Lipoproteins" refers to polypeptides that are associated non-covalently with lipids in the bloodstream and are capable of binding to cellular receptors.

- 5 Preferably, lipoproteins are those involved with transport and storage of lipids. Such proteins include, for example, chylomicrons, low density lipoprotein (LDL), very low density lipoprotein (VLDL), intermediate density lipoprotein (IDL), and high density lipoprotein (HDL). Also, included in the term are mutants, fragments, or fusions of the naturally occurring lipoproteins. Also,
- 10 modifications of naturally occurring lipoproteins can be used, such as acetylated LDL.

Mutants, fragments, fusions, or modifications of the naturally occurring lipoproteins are amino acid sequences that exhibit substantial sequence identity to naturally occurring lipoproteins or a fragment thereof. These polypeptides 15 will retain more than about 80% amino acid identity; more typically, more than about 85%; even more typically, at least 90%. Preferably, these polypeptides will exhibit more than about 92% amino acid sequence identity with naturally occurring lipoproteins or fragment thereof; more preferably, more than about 94%; even more preferably, more than about 96%; even more preferably, more 20 than about 98%; even more preferably, more than about 99%. All of these polypeptides exhibit receptor binding properties of naturally occurring lipoproteins. Usually, such polypeptides exhibit at least about 20% receptor binding of naturally occurring lipoproteins. More typically, the polypeptides exhibit at least about 40%, even more typically the polypeptides exhibit at least 25 about 60%; even more typically, at least about 70%; even more typically, at least about 80%; even more typically, at least about 85%; even more typically, at least about 90%; even more typically, at least about 95% receptor binding of the naturally occurring lipoproteins.

"Polynucleotide binding molecule" refers to those compounds that 30 associate with polynucleotides, and the association is not sequence specific. For example, such molecules can (1) aid in neutralizing the electrical charge of polynucleotide, or (2) facilitate condensation of nucleotides, or (3) inhibit serum or nuclease degradation.

"Polycationic agent" refers generally to a polymer comprising positively-charged single units, although some non-positively charged units may be present in the polymer. The instant agents exhibit a net positive charge under physiologically relevant pH. Such agents are capable of neutralizing the charge 5 of nucleic acids and can exhibit additional properties, such as condensation and/or serum protection of nucleic acids. Preferably, the agents comprises both amino acids and NSGs as monomeric units; also, preferred are agents comprising NSGs as monomeric units.

"Physiologically relevant pH" varies somewhat between *in vitro* and *in vivo* applications. Typically, the physiological pH is at least 5.5; more typically, 10 at least 6.0; even more typically, at least 6.5. Usually, physiologically relevant pH is no more than 8.5; more usually, no more than 8.0; even more usually, no more than 7.5.

"Polynucleotide" or "nucleic acid" refers to DNA, RNA, analogues 15 thereof, peptide-nucleic acids, and DNA or RNA with non-phosphate containing nucleotides. Additionally, these nucleic acids may be single-stranded, double-stranded, or chimeric single- or double-stranded molecules.

The term "oligomer" includes polymers such as poly NSGs, produced by the submonomer process described herein and also in Zuckermann *et al.*, supra. 20 includes polymers, copolymers, and interpolymers of any length. More specifically, oligomers may comprise a single repeating monomer, two alternating monomer units, two or more monomer units randomly and/or deliberately spaced relative to each other. Regardless of the type of polyamide produced, the polyamide of the invention may be produced by the same general 25 procedure which includes repeating a two-step or three step cycle wherein a new monomer unit is added in each cycle until an oligomer of desired length is obtained. The oligomer is preferably 2-100 monomers, more preferably 2-50, or 18-28 monomers or 24 to 48 monomers in length.

The term "frequency of uptake of polynucleotides into a cell" refers to an 30 increase in the amount of polynucleotides actually taken up by a cell relative to the amount actually administered to the cell. The frequency of uptake of polynucleotides into a cell is increased if it is greater than the frequency of uptake of naked polynucleotides. For example, using *in vitro* transfection

methods, uptake of naked polynucleotides into mammalian cells is not usually detectable over background. Some frequency of uptake, however, can be detected when naked polynucleotides are delivered *in vivo*. The frequency of uptake *in vivo* and *in vitro* depends on the tissue type. The frequency of uptake 5 can be measured by known methods for detecting the presence of polynucleotides, such as Northern, Southern, or Polymerase Chain Reaction (PCR) techniques.

Usually, a composition or compound is capable of increasing the frequency of polynucleotide uptake into a cell if it induces a frequency of uptake 10 that is at least 10% greater than the frequency of naked polynucleotide uptake; more usually, at least 15% greater; even more usually, 20% greater; even more usually, at least 30%; and up to 40% to 100% greater, and even 1,000% and 10,000% greater.

"Naked polynucleotides" refers to polynucleotides that are substantially 15 free from any delivery vehicle that can act to facilitate entry into the cell. For example, polynucleotides are naked when free from any material which promotes transfection, such as liposomal formulations, charged lipids, such as Lipofectin® or precipitating agents such as $\text{Ca}_3(\text{PO}_4)_2$.

"Effective amount to increase the frequency of polynucleotide uptake into 20 cells" refers to an amount that induces a frequency of polynucleotide uptake into a cell that is at least 10% greater than the frequency of naked polynucleotide uptake; more usually, at least 15% greater; even more usually, 20% greater; even more usually, at least 30%; even more usually, at least 40%.

"Effective amount to neutralize nucleic acids" refers to the amount used 25 to neutralize at least 10% of the electrical charge of the nucleic acid composition; more preferably; the amount refers to the amount used to neutralize at least 40%; even more preferably, the amount to neutralize 50% of the electrical charge; even more preferably, the amount to neutralize 60% of the electrical charge; even more preferably, the amount to neutralize 70% of the electrical charge; even 30 more preferably, the amount to neutralize 80% of the electrical charge; and most preferably, at least 90% of the electrical charge of the nucleic acid composition of interest.

"Condensation of nucleic acids" occurs when the polycationic agent that is combined with nucleic acids, neutralizes the electrical charge of the nucleic acids and causes it to assume a reduced structure relative to uncomplexed nucleic acids. Preferably, condensation reduces the structure of nucleic acids to a size 5 that can be internalized by structures present on cell surface membranes.

Condensation can be measured by determining the charge of the nucleic acid/polycationic agent by gel electrophoresis, for example. Alternatively, an effective amount to condense nucleic acids can also be measured by the final size of the polycationic agent/nucleic acid complex.

10 "Effective amount to inhibit serum or nuclease degradation of nucleic acids" refers to the amount used to increase the half-life of the polynucleotide when exposed to serum and/or nucleases by at least 5 minutes as compared the uncomplexed nucleic acids; more preferably, the amount used to inhibit degradation by at least 10 minutes; even more preferably, the amount used to 15 inhibit degradation by at least 30 minutes; even more preferably, the amount used to inhibit degradation by at least 45 minutes; even more preferably, the amount used to inhibit degradation by at least 60 minutes; even more preferably, the amount used to inhibit degradation by at least 90 minutes; and more preferably, the amount used to inhibit degradation by at least 120 minutes.

20 A composition containing A is "substantially free of" B when at least 85% by weight of the total A+B in the composition is A. Preferably, A comprises at least about 90% by weight of the total of A+B in the composition, more preferably at least about 95% or even 99% by weight.

25 "Immunogenicity" refers to the ability of a given molecule or a determinant thereof to induce the generation of antibodies with binding capacity to the molecule upon administration *in vivo*, to induce a cytotoxic response, activate the complement system, induce allergic reactions, and the like. An immune response may be measured by assays that determine the level of specific antibodies in serum, by assays that determine the presence of a serum component 30 that inactivates the polycationic agent/nucleic acid complex or conjugated gene delivery vehicle, or by other assays that measure a specific component or activity of the immune system. As discussed in more detail below, low immunogenicity may be established by these assays. The terms "low immunogenicity," "reduced

"immunogenicity," "lowered immunogenicity" and similar terms are intended to be equivalent terms.

An "origin of replication" is a polynucleotide sequence that initiates and regulates replication of polynucleotides, such as an expression vector. The origin of replication behaves as an autonomous unit of polynucleotide replication within a cell, capable of replication under its own control. With certain origins of replication, an expression vector can be reproduced at a high copy number in the presence of the appropriate proteins within the cell. Examples of origins are the 2 μ and autonomously replicating sequences, which are effective in yeast; and the viral T-antigen, effective in COS-7 cells.

General Methods and Detailed Description

POLYNUCLEOTIDES

Polynucleotides used in the instant invention can be used to express desired polypeptides, or can be, in themselves, therapeutic, such as ribozymes or antisense polynucleotides. Such polynucleotides can be used in *in vitro*, *ex vivo*, and *in vivo* applications.

Also, the polynucleotides of the invention can be vectors that express polypeptides, ribozymes, or antisense molecules. Vectors contain at least a promoter to initiate transcription operably linked to the coding region, ribozyme or antisense molecule. Other components that can be included in the vector are, for example: (1) a terminator sequence; (2) a sequence encoding a leader peptide to direct secretion; (3) a selectable marker; and (4) an origin of replication.

An origin of replication is not necessary. The polynucleotides to be delivered can be either replicating or non-replicating. Other components can be added as desired and convenient.

The polynucleotides and methods of the invention can be utilized with any type of host cell. The choice of promoter, terminator, and other optional elements of an expression vector will depend on the host cell chosen. The invention is not dependent on the host cell selected. Convenience and the desired level of protein expression will dictate the optimal host cell. A variety of hosts for expression are known in the art and available from the American Type Culture Collection (ATCC) (Rockville, Maryland, U.S.A.). Suitable bacterial

hosts suitable include, without limitation: *Campylobacter*, *Bacillus*, *Escherichia*, *Lactobacillus*, *Pseudomonas*, *Staphylococcus*, and *Streptococcus*. Yeast hosts from the following genera may be utilized: *Candida*, *Hansenula*, *Kluyveromyces*, *Pichia*, *Saccharomyces*, *Schizosaccharomyces*, and *Yarrowia*.

5 *Aedes aegypti*, *Bombyx mori*, *Drosophila melanogaster*, and *Spodoptera frugiperda* (PCT Patent Publication No. WO 89/046699; Carbonell *et al.*, 1985, *J. Virol.* 56:153; Wright, 1986, *Nature* 321:718; Smith *et al.*, 1983, *Mol. Cell. Biol.* 3:2156; and see generally, Fraser *et al.*, 1989, *In Vitro Cell. Dev. Biol.* 25:225).

10 Useful mammalian cell types for *in vitro* applications include for example, those cell lines available from the American Type Culture Collection (ATCC), Chinese hamster ovary (CHO) cells, HeLa cells, baby hamster kidney (BHK) cells, monkey kidney cells (COS), human hepatocellular carcinoma cells (e.g., Hep G2), human embryonic kidney cells, baby hamster kidney cells, mouse sertoli cells, canine kidney cells, buffalo rat liver cells, human lung cells, human liver cells, mouse mammary tumor cells, as well as others.

15 20

Useful cell types for *in vivo* or *ex vivo* applications include, without limitation, any tissue type, such as muscle, skin, brain, lung, liver, spleen, blood, bone marrow, thymus, heart, lymph, bone, cartilage, pancreas, kidney, gall bladder, stomach, intestine, testis, ovary, uterus, rectum, nervous system, eye, gland, and connective tissue.

A. *In vitro and Ex vivo Vectors*

The polynucleotides encoding the desired polypeptides or ribozymes, or antisense polynucleotides can be transcribed and/or translated using the following promoters and enhancers as examples. The examples include, without limitation: the 422(aP2) gene and the stearoyl-CoA desaturase 1 (SCD1) gene, which contains suitable adipocyte-specific promoters, as described in Christy *et al.*, 1989, *Genes Dev.* 3:1323-1335. Synthetic non-natural promoters or hybrid promoters can also be used herein. For example, a T7T7/T7 promoter can be constructed and used, in accordance with Chen *et al.*, 1994, *Nucleic Acids Res.* 22:2114-2120, where the T7 polymerase is under the regulatory control of its own promoter and drives the transcription of a polynucleotide sequence, which is

placed under the control of another T7 promoter. The primary determinant for the fat-specific expression is an enhancer located at about >5 kb upstream of the transcriptional start site, as described in Ross *et al.*, 1990, Proc. Natl. Acad. Sci. USA 87:9590-9594 and Graves *et al.*, 1991, Genes Dev. 5:428-437. Also 5 suitable for use herein is the gene for the CCAAT/enhancer-binding protein C/EBP α , which is highly expressed when 3T3-L1 adioblast commit to the differentiation pathway and in mature post-mitotic adipocytes, as described in Birkenmeier *et al.*, 1989, Gene Dev. 3:1146-1156. The recently isolated transcription factor PPAR γ 2, expressed exclusively in adipocyte tissues, as 10 described in Tontonoz *et al.*, 1994, Cell 79:1147-1156, can also be used herein.

Typical promoters for mammalian cell expression include the SV40 early promoter, the CMV promoter, the mouse mammary tumor virus LTR promoter, the adenovirus major late promoter (Ad MLP), and the herpes simplex virus promoter, among others. Other non-viral promoters, such as a promoter derived from the murine 15 metallothionein gene, will also find use in mammalian constructs. Expression may be either constitutive or regulated (inducible), depending on the promoter. Typically, transcription termination and polyadenylation sequences will also be present, located 3' to the translation stop codon. Preferably, a sequence for optimization of initiation of translation, located 5' to the coding sequence, is also present. Examples of transcription 20 terminator/polyadenylation signals include those derived from SV40, as described in Sambrook *et al.*, 1989, "Molecular Cloning, A Laboratory Manual," second edition, Cold Spring Harbor Press, Cold Spring Harbor, New York. Introns, containing splice donor and acceptor sites, may also be designed into the constructs of the present invention.

Enhancer elements can also be used herein to increase expression levels of the 25 mammalian constructs. Examples include the SV40 early gene enhancer, as described in Dijkema *et al.*, 1985, EMBO J. 4:761, and the enhancer/promoter derived from the long terminal repeat (LTR) of the Rous Sarcoma Virus, as described in Gorman *et al.*, 1982b, Proc. Natl. Acad. Sci. USA 79:6777, and human cytomegalovirus, as described in Boshart *et al.*, 1985, Cell 41:521. A leader sequence can also be present which includes a 30 sequence encoding a signal peptide, to provide for the secretion of the foreign protein in mammalian cells. Preferably, there are processing sites encoded between the leader fragment and the gene of interest such that the leader sequence can be cleaved either *in vivo* or *in vitro*.

Other regulatory regions from viruses can be included in the polynucleotides of the instant invention to increase transcription and translation levels or increase the duration of transcription and translation. For example, the long terminal repeats of HIV can be included. Alternatively, the inverted terminal repeats of the Epstein Barr Virus can
5 be used.

There exist expression vectors that provide for the transient expression in mammalian cells of DNA encoding the target polypeptide. In general, transient expression involves the use of an expression vector that is able to replicate efficiently in a host cell, such that the host cell accumulates many copies of the
10 expression vector and, in turn, synthesizes high levels of a desired polypeptide encoded by the expression vector. Transient expression systems, comprising a suitable expression vector and a host cell, allow for the convenient positive identification of polypeptides encoded by cloned DNAs, as well as for the rapid screening of such polypeptides for desired biological or physiological properties.
15 Thus, transient expression systems are particularly useful for purposes of identifying analogs and variants of the target polypeptide that have target polypeptide-like activity.

B. In vivo Vectors

For delivery using viral vectors, any of a number of viral vectors can be used, as described in Jolly, 1994, Cancer Gene Therapy 1:1-64. For example, the coding sequence of a desired polypeptide or ribozymes or antisense molecules can be inserted into plasmids designed for transcription and/or translation in retroviral vectors, as described in Kimura et al., 1994, Human Gene Therapy 5:845-852, adenoviral vectors, as described in Connelly et al., 1995, Human Gene Therapy 6:185-193, adeno-associated viral vectors, as described in Kaplitt et al., 1994, Nature Genetics 6:148-153 and sindbis vectors. Promoters that are suitable for use with these vectors include the Moloney retroviral LTR, CMV promoter and the mouse albumin promoter. Replication competent free virus can be produced and injected directly into the animal or humans or by transduction
30 of an autologous cell *ex vivo*, followed by injection *in vivo* as described in Zatloukal et al., 1994, Proc. Natl. Acad. Sci. USA 91:5148-5152.

The polynucleotide encoding a desired polypeptide or ribozyme or antisense polynucleotide can also be inserted into plasmid for expression of the desired polypeptide *in vivo*. For *in vivo* therapy, the coding sequence can be delivered by direct injection into tissue, or via oral administration as an aerosol.

- 5 Promoters suitable for use in this manner include endogenous and heterologous promoters such as CMV. Further, a synthetic T7T7/T7 promoter can be constructed in accordance with Chen *et al.*, 1994, Nucleic Acids Res. 22:2114-2120, where the T7 polymerase is under the regulatory control of its own promoter and drives the transcription of polynucleotide sequence, which is also placed under the control of a T7 promoter. The polynucleotide can be injected in a formulation that can stabilize the coding sequence and facilitate transduction thereof into cells and/or provide targeting, as described in Zhu *et al.*, 1993, Science 261:209-211.
- 10

15 Expression of the coding sequence of a desired polypeptide or replication of a ribozyme or antisense polynucleotide *in vivo* upon delivery for gene therapy purposes by either viral or non-viral vectors can be regulated for maximal efficacy and safety by use of regulated gene expression promoters as described in Gossen *et al.*, 1992, Proc. Natl. Acad. Sci. USA 89:5547-5551. For example, the polynucleotide transcription and/or translation can be regulated by tetracycline responsive promoters. These promoters can be regulated in a positive or negative fashion by treatment with the regulator molecule.

20

For non-viral delivery of the coding sequence of the desired polypeptide, the sequence can be inserted into conventional vectors that contain conventional control sequences for high level expression.

C. Preferred Vector

A preferred vector comprises: (1) an (EBV) origin of replication or a BKV (BK virus), a parvovirus, origin of replication; (2) a coding region for an EBV or BKV origin binding protein; (3) at least one inverted terminal repeat; (4) 5 a promoter; (5) an enhancer; (6) a terminator; (7) optionally, a selectable marker.

Preferably, the origin of replication is EBV ori p; more preferably, nucleotides 2623 to 4559 of SEQ ID NO:1 are utilized. The sequence is obtainable from vector pCEP4, commercially available from Invitrogen, San Diego, California, USA.

10 Preferably, the coding region encodes the EBV nuclear antigen A, which binds to EBV ori p; more preferably, the polynucleotide sequence is nucleotides 14 to 2594 of SEQ ID NO:1 are utilized. The sequence is obtainable from vector pCEP4, commercially available from Invitrogen, San Diego, California, USA.

15 Fragments and mutants of the preferred origin and binding protein capable of initiating replication of the vector in the desired host cell can be utilized. Preferably, the fragments and mutants will retain more than about 80% sequence identity with nucleotides 14 to 2594 or 2623 to 4559 of SEQ ID NO:1 or fragment thereof; more typically, more than about 85%; even more typically, at least 90%. Preferably, these polynucleotides exhibit more than about 92% 20 sequence identity with nucleotides 14 to 2594 or 2623 to 4559 of SEQ ID NO:1 or fragment thereof; more preferably, more than about 94%; even more preferably, more than about 96%; even more preferably, more than about 98%; even more preferably, more than about 99%.

25 Preferably, the inverted terminal repeats are those sequences found in adenovirus (AV) or adeno-associated virus (AAV); more preferably, the inverted terminal repeats are those found in AAV; even more preferably, the polynucleotide sequence is 4938 to 5104 or 7189 to 7355 of SEQ ID NO: 1. The sequence of AAV is described in Samulski *et al.*, 1987, *J. Virol.* **61**:3096-3101.

30 Fragments and mutants of the preferred inverted terminal repeat capable of initiating replication of the vector in the desired host cell can be utilized. Preferably, the fragments and mutants will retain more than about 80% sequence identity with nucleotides 4938 to 5104 or 7189 to 7355 of SEQ ID NO: 1 or fragment thereof; more typically, more than about 85%; even more typically, at

least 90%. Preferably, these polynucleotides exhibit more than about 92% sequence identity with nucleotides 4938 to 5104 or 7189 to 7355 of SEQ ID NO: 1 or fragment thereof; more preferably, more than about 94%; even more preferably, more than about 96%; even more preferably, more than about 98%; even more preferably, more than about 99%.

Preferably, the cytomegalovirus enhancer/promoter is utilized; more preferably, the CMV promoter sequence is nucleotide sequence 5112 to 6734 of SEQ ID NO:1.

Mutants and fragments of the preferred enhancer and promoter capable of initiating transcription and/or translation can be utilized. Preferably, the fragments and mutants will retain more than about 80% sequence identity with nucleotides 5112 to 6734 of SEQ ID NO: 1 or fragment thereof; more typically, more than about 85%; even more typically, at least 90%. Preferably, these polynucleotides exhibit more than about 92% sequence identity with nucleotides 5112 to 6734 of SEQ ID NO: 1 or fragment thereof; more preferably, more than about 94%; even more preferably, more than about 96%; even more preferably, more than about 98%; even more preferably, more than about 99%.

A preferred terminator is the bovine growth hormone poly A sequence; more preferably, the polynucleotide sequence is nucleotide 6818 to 7050 of SEQ ID NO:1.

Mutants and fragments of the preferred terminator capable of terminating transcription and/or translation can be utilized. Preferably, the fragments and mutants will retain more than about 80% sequence identity with nucleotides 6818 to 7050 of SEQ ID NO: 1 or fragment thereof; more typically, more than about 85%; even more typically, at least 90%. Preferably, these polynucleotides exhibit more than about 92% sequence identity with nucleotides 6818 to 7050 of SEQ ID NO: 1 or fragment thereof; more preferably, more than about 94%; even more preferably, more than about 96%; even more preferably, more than about 98%; even more preferably, more than about 99%.

The sequence of the preferred vector is shown in SEQ ID NO:1. Polynucleotides encoding polypeptides, such as erythropoietin or leptin, and ribozymes and antisense polynucleotides can be inserted into the vector.

D. Examples of Coding Regions, Ribozymes, and Antisense Molecules

The following are examples of coding regions, ribozymes, and antisense molecules that can be used to treat various indications in mammals. The nucleotide sequence of the genes of interest can be found, for example, in publicly available databases, such as Genbank. Polynucleotides to be delivered can be used to treat viral infections or chronic pathogen infection.

1. Hemophilia

Gene replacement by *in vivo* delivery of polynucleotides can be effective in treating hemophilia. The following are examples of polypeptides that can be encoded by the polynucleotides to be delivered: Factor VIII:C, mutants of Factor VIII:C, preferably those that are uncleavable. Also, useful to treat hemophilia are ribozyme and antisense polynucleotides as inhibitors of Tissue Factor Plasminogen Inhibitor (TFPI).

The routes of delivery for treating hemophilia include, for example, intravenous/intrahepatic injection, *ex vivo* transduction of stem cells or lymphocytes using retroviral vectors.

2. Treatment of Graft Versus Host Disease

In vivo delivery of polynucleotides encoding prodrugs can be used for direct ablation to treat graft versus host disease in, for example, leukemia bone marrow transplantation. Herpes thymidine kinase in conjunction with gancyclovir can be utilized for this purpose. Other examples of prodrugs are described in the cancer section.

The routes of delivery for treating graft versus host disease include, for example, *ex vivo* transduction of T-lymphocytes using retroviral vectors.

25 3. Vaccines

In vivo delivery of polynucleotides encoding a desired antigen can be utilized to induce an immune response. This response can include both cellular and humoral response. This type of vaccine can be used to treat cancer as well as infectious diseases. Further, such treatment can be either prophylactic or therapeutic immunotherapy.

Examples of infectious diseases include, Human Immunodeficiency Virus (HIV), Hepatitis A, B, C, etc., (HAV, HBV, HCV, etc.), Human Papiloma Virus (HPV), cytomegalovirus (CMV), herpes simplex 1 and 2 (HSV), etc. Preferred antigens include non-structural proteins 3, 4a, and 5b (NS3, NS4, and 5 NSSb) of HCV; gB2 and gD2 of HSV; env and rev proteins of HIV.

Also, cancer antigens can be used in vaccines, for both therapeutic and prophylactic purposes.

The antigens can be presented in the context of Class I major histocompatibility antigens, or to induce a cellular cytotoxic T cell response, or 10 to induce a humoral response comprising the synthesis of antibodies.

In addition, an antisense or ribozyme target to a immune suppressive molecule, IL-10, TGF- β , and CTLA-4, for example, can be useful to be administered with a vaccine.

The routes of delivery for vaccines include, for example, intramuscular 15 injection, dendritic cell-based immunization, or oral immunization by both viral and non-viral vectors.

4. Diabetes Mellitus

Diabetes is another indication that can be treated by *in vivo* delivery of a replacement gene. The following are examples of useful polypeptides to be 20 encoded by the replacement gene: insulin, insulin-like growth factor I and II (IGF-I and II).

Also useful for treating diabetes are polynucleotides encoding IAS-L, found on the surface of B cells in the pancreas, to protect the cells from immune destruction.

25 The routes of delivery for treating diabetes include, for example, liver-directed, parotid- directed, pancreas-directed, salivary gland-directed using both viral and non-viral vectors.

5. Hyperlipidemia

Hyperlipidemia can be treated by *in vivo* delivery of the following 30 polynucleotides encoding apoproteins or lipoprotein receptors. A more extensive description of lipoproteins and apoproteins is provided below.

The routes of delivery for treating hyperlipidemia include, for example, liver-directed intravenous administration by both viral and non-viral vectors.

6. Myocardial Ischemia or Infarction

The following are examples of polynucleotides that are useful, when delivered *in vivo*, to treat myocardial ischemia or infarction:

polynucleotides encoding basic fibroblast growth factor (bFGF), fibroblast growth factor 5 (FGF-5) and IGF-I.

The routes of delivery for treating myocardial ischemia or infarction include, for example, intrapericardial delivery of viral vector or non-viral vectors.

7. Bowel Disease

The following are examples of polynucleotides that can be delivered *in vivo* to treat bowel disease:

- (i) ribozymes or antisense polynucleotides as inhibitors of macrophage/inflammatory cell recruitment or activation, such as NF κ B;
- (ii) ribozymes or antisense polynucleotides to act as anti-apoptotic agents, such as inhibitors of interleukin 1b converting enzyme family;
- (iii) polynucleotides encoding complement blockers, such as decay accelerating factor (DAF), membrane cofactor protein (MCP); and the fusions of DAF and MCP also known as CAB-2;
- (iv) cyclooxygenase inhibitors;
- (v) anti-proliferative agents, such as, ribozymes, antisense oligonucleotides, antibodies, protein, or peptides against c-myb, ras/raf, PI3 kinase, cyclins;
- (vi) polynucleotides encoding suicide proteins/genes, such as, herpes thymidine kinase;
- (vii) polynucleotides encoding replacement genes or proteins which maybe deficient or down regulated during the development of inflammatory bowel disease.
- (viii) polynucleotides encoding IkB.

8. Prostate Cancer and Benign Prostatic Hyperplasia

The following polynucleotides can be delivered to treat prostate cancer and benign prostatic hyperplasia:

- (i) a polynucleotide encoding a pro-apoptotic agent, including for example, fas, fas ligand, fadd, fap-1, tradd,faf, rip, reaper, apoptin, interleukin-2 converting enzyme;
- (ii) a polynucleotide encoding an anti-angiogenic agent, including, for example, bFGF soluble receptor and fragments, angiostatin, transforming growth factor- β (TGF- β), interferon- α (IFN α), proliferin-related protein, a urokinase plasminogen activator receptor antagonist, platelet factor 4 (PF4), thrombospondin, a tissue inhibitor of metalloproteinase, and prolactin;
- (iii) a polynucleotide encoding a immunomodulating agent including, for example, interleukin-2 (IL-2), IFN α , IFN β , IFN γ , granulocyte macrophage-colony stimulating factor (GM-CSF), and macrophage-colony stimulating factor (M-CSF);
- (iv) a ribozyme or antisense polynucleotide as an antiproliferative agent including, for example, an inhibitor of a signal transduction pathway, for example, an inhibitor of a signal transduction pathway mediated by myb, ras, ras superfamily, raf, phosphoinositol (PI3-kinase), a phosphotyrosine binding (PTB) domain, a SRC homology-2 (SH2) domain, a SRC homology-3 (SH3) domain, a plexin homology (PH) domain, JUN kinase, and a stress activated kinase, signaling inositol phosphatases; and an inhibitor of a cyclin;
- (v) a ribozyme or antisense polynucleotide as an inhibitor of a growth factor or inhibitor of a receptor of a growth factor, including, for example, epidermal growth factor (EGF), TGF- α , FGF, TGF- β , platelet derived growth factor (PDGF), keratinocyte growth factor (KGF), or any prostate cell specific growth factor;
- (vi) a polynucleotide encoding a tumor suppressor gene or a gene down-regulated during the onset of a hyperplastic condition in the prostate; and
- (vii) an antisense or ribozyme target to a immune suppressive molecule, IL-10, TGF- β , and CTLA-4, for example.

9. Anemia, Leukopenia, and Thrombocytopenia

Anemia can be treated by *in vivo* delivery of a polynucleotide encoding erythropoietin, GM-CSF-, G-CSF, M-CSF, and thrombopoietin, for example. Examples of delivery routes for this indication include without limitation: liver-targeted intravenous administration of viral vectors and non-viral vectors. See 5 the Examples below.

10. Cardiomyopathy

The following are examples of polynucleotides that can be delivered *in vivo* to treat cardiomyopathy: polynucleotides encoding, IGF-1, L-amino acid 10 decarboxylas, inhibitors of β adrenergic receptor kinases (BARK), troponin, and β adrenergic receptors.

Examples of delivery routes for this indication include, without 15 limitation, pericardial expression of IGF-1, and for the other genes, intramycardial injection or myocardial targeting via intracoronary injection or intrapericardial administration of viral vectors or non-viral vectors.

11. Rheumatoid Arthritis

The following are examples of polynucleotides that can be delivered *in vivo* to treat rheumatoid arthritis, polynucleotides encoding a prodrug, such as herpes thymidine kinase, MMP inhibitors, fas, and pro-apoptotic proteins, 20 described above, and interleukin-1 receptor A, interleukin-10, IkB.

Also, antisense and ribozyme polynucleotides as inhibitors of NF κ B.

Examples of delivery routes for this indication include, without limitation, intraarticular injection of viral and non-viral vectors.

12. Osteoarthritis and Psoriasis

25 The following are examples of polynucleotides that can be delivered *in vivo* to treat osteoarthritis and psoriasis: polynucleotides encoding IGF-1; ribozyme and antisense polynucleotides as inhibitors of metalloproteinase inhibitors.

Also, the following are examples of polynucleotides that can be delivered 30 *in vivo* to treat osteoarthritis and psoriasis, polynucleotides encoding a prodrug.

such as herpes thymidine kinase, MMP inhibitors, fas, and pro-apoptotic proteins, described above, and interleukin-1 receptor A, interleukin-10, I_KB.

Also, antisense and ribozyme polynucleotides as inhibitors of NF_κB.

Examples of delivery routes for this indication include, without limitation, intraarticular injection.

13. Restenosis

The following are examples of polynucleotides that can be delivered *in vivo* to treat restenosis:

- (i) polynucleotides encoding a prodrug, such as thymidine kinase, other examples are described in the cancer section;
- (ii) polynucleotides encoding tissue factor plasminogen inhibitor (TFPI);
- (iii) polynucleotides encoding c-myb rbz, c-ras rbz,
- (iv) polynucleotides encoding pro-apoptotic agents, described above;
- (v) polynucleotides encoding I_KB.

Examples of delivery routes for this indication include, without limitation, intracoronary delivery of viral and non-viral vectors.

14. Cancer

The gene delivery vectors of the invention are useful in delivering therapeutic genes for treatment of hyperproliferative disorders, including malignancy, for treatment of infectious disease and for treatment of inflammatory diseases, including autoimmune disease. For instance, the gene therapy vectors can be used to express cytokines or proteins that convert an inactive or partially active prodrug into an active drug. In many cases, conversion of the prodrug into its active form results in a compound with cytolytic activity.

a. Prodrug converting enzymes

A number of "suicide genes" which encode different proteins useful in prodrug conversion can be used in the instant invention. For instance, nucleoside kinases such as thymidine kinase are particularly useful. In particular, the HSV-

TK system has important advantages for anti-tumor cell therapy. See PCT publication number WO 91/02805 entitled "Recombinant Retroviruses Delivering Vector Constructs to Target Cells" and PCT publication number WO 95/14014091 entitled "Compositions and Methods for Utilizing Conditionally Lethal Genes" for a description of treatment of cancer and other diseases by gene delivery vectors expressing thymidine kinase and other prodrug converting enzymes. HSV-TK transduced tumor cells can mediate a significant bystander killing effect on untransduced neighboring cells *in vitro* and *in vivo* (Moolten *et al.*, supra, Freeman *et al.*, 1993, Cancer Res. **53**:5274), most commonly as a result of transfer to the toxic ganciclovir metabolite, GCV triphosphate, between adjacent cells through intercellular gap junctions (Bi *et al.*, 1993, Human Gene Therap. **4**:725). Endothelial cells in capillary walls are connected by gap junctions, so a dramatic bystander effect created by GCV-triphosphate transfer between neighboring endothelial cells and the massive amplification effects of the clotting cascade and the tumor to endothelial cell ratio could ensue (Denekamp *et al.*, 1986, Cancer Topics **6**:6; Denekamp *et al.*, 1984, Prog. Appl. Microcir. **4**:28). Recent evidence suggests that the occasional transduction of tumor endothelial cells during intralesional therapy with HSV-TK retroviral vectors may account for a significant component of the antitumor activity of the vectors (Ram *et al.*, 1994, J. Neurosurg. **81**:256). In addition, the suicide gene is only conditionally cytotoxic to the target cells (*i.e.* only when GCV is given). Consequently, an *ex vivo* administration method can be utilized. For example, in this type of protocol, endothelial cells may be isolated from tumor biopsies (Medzelewski *et al.*, 1994, Cancer Res. **54**:336), induced to proliferate with appropriate mitogens (Ferrara *et al.*, supra) and transduced with TK *in vitro*. Transplanted EC become incorporated into the neovasculature in days to weeks after intratumoral injection (Lal *et al.*, 1994, Cancer Gene Therap. **1**:322), so GCV treatment would follow a suitable 'lag phase' to allow the transduced EC to integrate functionally into the tumor vasculature. The two-step enzyme-prodrug system offers greater flexibility of delicate clinical management, because cessation of GCV infusion in the event of (potentially very serious) complications arising from damage to normal EC, would block toxicity without the need to block transgene activity *in situ*.

A number of alternative 'suicide genes' in addition to thymidine kinase may also be useful for cancer gene therapy (Moolten *et al.*, *supra*). Introduction of the bacterial cytosine deaminase gene (Huber *et al.*, 1993, *Cancer Res.* 53:4619) into tumor cells confers sensitivity to the antifungal agent 5-fluorocytosine (5-FC). Cytosine deaminase converts 5-FC to 5-fluorouracil (5-FU, Nishiyama *et al.*, 1985, *Cancer Res.* 45:1753). Since 5-FU is commonly used chemotherapeutic drug for breast cancer, several groups have developed cytosine deaminase-based 'suicide gene' therapy models for this disease. Tumor specificity may be further increased by introducing the c-erbB2 promoter/enhancer elements 5' to the cytosine deaminase gene, so that the therapeutic transgene is preferentially transcribed in c-erbB2-overexpressing breast tumor cells (Harris *et al.*, 1994, *Gene Therap.* 1:170). Alkaline phosphatase has been widely explored as prodrug-activating enzyme in the related field of antibody directed enzymne-prodrug therapy (ADEPT). This enzyme has the advantage that it can activate a wide range of phosphorylated derivatives of anticancer agents (*e.g.* mitomycin C, etoposide, *etc.*) that cannot cross cell membranes until the charged phosphate group is cleaved off, so a single enzyme could generate *de novo* a cocktail of chemotherapeutic agents within the tumor mass (Senter *et al.*, 1993, *Bioconjugate Chem.* 4:3). Other suicide genes may encode a polypeptide or polypeptides (with a corresponding non-cytotoxic agent) such as Herpes Simpex virus thymidine kinase (gancyclovir or acyclovir), Varicella Zoster virus thymidine kinase (6 methoxypurine arabinonucleoside; Huber *et al.*, 1991, *Proc. Natl. Acad. Sci. USA* 88:8039), *E. coli* cytosine deaminase (fluorouracil; Mullen *et al.*, 1992, *Proc. Natl. Acad. Sci. USA* 89:33), *E. coli* xanthine-guanine phosphoribosyl transferase (thioxanthine; Beshard *et al.*, 1987, *Mol. Cell Biol.* 7:4139), *E. coli* or *Leishmania* purine nucleotide phosphorylase (various nontoxic purine deoxyadenosine, adenosine, deoxyguanosine, or guanosine derivatives (Koszalka and Krenitsky, 1979, *J. Biol. Chem.* 254:8185, 1979; Sorscher *et al.*, 1994, *Gene Therapy* 1:233), cytochrome p450 2B1 or cytochrome p450 reductase (*e.g.*, 3amino-1,2,4 benzotriazine 1,4-dioxide (Walton *et al.*, 1992, *Biochem. Pharmacol.* 44:251), cell surface alkaline phosphatase (*e.g.*, etoposide monophosphate; Senter *et al.*, 1988, *Proc. Natl. Acad. Sci. USA* 85:4842, 1988), nitroreductase (*e.g.*, metronidazole or

nitrofuranoin; Hof *et al.*, 1988, Immunitat und Infektion 16:220), N-deoxyribosy transferase (1-deazapurine; Betbeder *et al.*, 1989, Nucleic Acids Res 17:4217), pyruvate ferrodoxin oxidoreductase (metronidazol; Upcroft *et al.*, 1990, Int. J. Parasitolog. 20:489), carboxypeptidase G2 (aminoacylate nitrogen mustards; 5 Antoniw *et al.*, 1990, Brit J. Cancer 62:909), carboxypeptidase A (methotrexate alpha alanine; Haenseler *et al.*, 1992, Biochemistry 31:891), • lactamase (cephalosporin derivatives; Meyer *et al.*, 1993, Cancer Res. 53:3956; and Vradhula *et al.*, 1993, Bioconjugate Chemistry 4:334), Actinomycin D synthetase complex (synthetic pentapeptide lactone precursors; Katz *et al.*, 1990, 10 J. Antibiotics 43:231), and •-glucuronidase (various glucuronide derivatives of toxic drugs such as doxorubicin; Bosslet *et al.*, 1994, Cancer Res. 54:2151; Haeberlin *et al.*, 1993, Pharmaceutical Res. 10:1553).

Any of a variety of other enzymes which convert inactive prodrugs into active drugs and known to those of skill in the art can also used in the gene 15 delivery vehicles of the invention. For example, see PCT publication number WO 95/14014091 entitled "Compositions and Methods for Utilizing Conditionally Lethal Genes", and European Patent publication number EP90309430, entitled "Molecular Chimeras Useful for Cancer Therapy-- Comprising Regulatory Sequences and heterologous enzyme, e.g. Varicella 20 Zoster Virus Thymidine Kinase" for a description of additional prodrug/enzyme systems useful for gene therapy. As an additional example, see PCT Patent Publication No. WO 95/13095 entitled "New Prodrugs and Enzyme Targeting Molecule Conjugates--Useful in Antibody Direct Enzyme Prodrug Therapy of e.g. Viral Infections".

A variety of tumors may be targeted for treatment by the gene delivery 25 vehicles of the invention. In general, solid tumors are preferred, although leukemias and lymphomas may also be treated if they have developed a solid mass, or if suitable tumor associated markers exist such that the tumor cells can be physically separated from nonpathogenic normal cells. Representative 30 examples of suitable tumors include melanomas, colorectal carcinomas, lung carcinomas (including large cell, small cell, squamous and adeno-carcinomas), renal cell carcinomas and breast adeno-carcinomas. Gene delivery vehicles expressing thymidine kinase and other prodrug converting enzymes are also

useful in the treatment of autoimmune diseases including rheumatoid arthritis, osteoarthritis and graft vs. host disease. See e.g. PCT Patent Publication No. WO 95/14091, entitled "Compositions and Methods for Utilizing Conditionally Lethal Genes," for a description of treatment of disease with gene therapy vectors expressing prodrug converting enzymes.

5 b. Cytokines

A variety of polynucleotides encoding cytokines and immune system modulators can be delivered by the gene delivery vehicles of the invention for treatment of a number of different disorders. Representative examples include cytokines, such as IL-1, IL-2 (Karupiah *et al.*, 1990, *J. Immunology* **144**:290-298; Weber *et al.*, 1987, *J. Exp. Med.* **166**:1716-1733; Gansbacher *et al.*, 1990, *J. Exp. Med.* **172**:1217-1224; U.S. Patent No. 4,738,927), IL-3, IL-4 (Tepper *et al.*, 1989, *Cell* **57**:503-512; Golumbek *et al.*, 1991, *Science* **254**:713-716, 1991; U.S. Patent No. 5,017,691), IL-5, IL-6 (Brakenhof *et al.*, 1987, *J. Immunol.* **139**:4116-4121; WO 90/06370), IL-7 (U.S. Patent No. 4,965,195), IL-8, IL-9, IL-10, IL-11, IL-12, IL-13 (*Cytokine Bulletin*, Summer 1994), IL-14 and IL-15, particularly IL-2, IL-4, IL-6, IL-12, and IL-13, alpha interferon (Finter *et al.*, 1991, *Drugs* **42**(5):749-765; U.S. Patent No. 4,892,743; U.S. Patent No. 4,966,843; WO 85/02862; Nagata *et al.*, 1980, *Nature* **284**:316-320; Familletti *et al.*, 1981, *Methods in Enz.* **78**:387-394; Twu *et al.*, 1989, *Proc. Natl. Acad. Sci. USA* **86**:2046-2050; Faktor *et al.*, 1990, *Oncogene* **5**:867-872), beta interferon (Seif *et al.*, 1991, *J. Virol.* **65**:664-671), gamma interferons (Radford *et al.*, *The American Society of Hepatology* 2008-2015, 1991; Watanabe *et al.*, 25 *PNAS* **86**:9456-9460, 1989; Gansbacher *et al.*, 1990, *Cancer Research* **50**:7820-7825; Maio *et al.*, 1989, *Can. Immunol. Immunother.* **30**:34-42; U.S. Patent No. 4,762,791; U.S. Patent No. 4,727,138), G-CSF (U.S. Patent Nos. 4,999,291 and 4,810,643), GM-CSF (WO 85/04188), tumor necrosis factors (TNFs) (Jayaraman *et al.*, 1990, *J. Immunology* **144**:942-951), CD3 (Krissanen *et al.*, 1987, *Immunogenetics* **26**:258-266, 1987), ICAM-1 (Altman *et al.*, 1989, *Nature* **338**:512-514; Simmons *et al.*, 1988, *Nature* **331**:624-627), ICAM-2, LFA-1, LFA-3 (Wallner *et al.*, 1987, *J. Exp. Med.* **166**(4):923-932), MHC class I molecules, MHC class II molecules, B7.1-.3, 2-microglobulin (Parnes *et al.*,

1981, Proc. Natl. Acad. Sci. **78**:2253-2257), chaperones such as calnexin, MHC linked transporter proteins or analogs thereof (Powis *et al.*, 1991, Nature **354**:528-531, 1991).

Genes encoding any of the cytokine and immunomodulatory proteins
5 described herein can be expressed in a gene delivery vehicle of the invention. Other forms of these cytokines which are known to those of skill in the art can also be used. For instance, nucleic acid sequences encoding native IL-2 and gamma-interferon can be obtained as described in U.S. Patent Nos. 4,738,927 and 5,326,859, respectively, while useful mutants of these proteins can be
10 obtained as described in U.S. Patent No. 4,853,332. As an additional example, nucleic acid sequences encoding the short and long forms of mCSF can be obtained as described in US Patent Nos. 4,847,201 and 4,879,227, respectively.

Other nucleic acid molecules that encode cytokines, as well as other nucleic acid molecules that are advantageous for use within the present
15 invention, may be readily obtained from a variety of sources, including, for example, depositories such as the American Type Culture Collection (ATCC, Rockville, Maryland), or from commercial sources such as British Bio-Technology Limited (Cowley, Oxford England). Representative examples include BBG 12 (containing the GM-CSF gene coding for the mature protein of
20 127 amino acids), BBG 6 (which contains sequences encoding gamma interferon), ATCC No. 39656 (which contains sequences encoding TNF), ATCC No. 20663 (which contains sequences encoding alpha interferon), ATCC Nos. 31902, 31902 and 39517 (which contains sequences encoding beta interferon), ATCC No 67024 (which contains a sequence which encodes Interleukin-1b),
25 ATCC Nos. 39405, 39452, 39516, 39626 and 39673 (which contains sequences encoding Interleukin-2), ATCC Nos. 59399, 59398, and 67326 (which contain sequences encoding Interleukin-3), ATCC No. 57592 (which contains sequences encoding Interleukin-4), ATCC Nos. 59394 and 59395 (which contain sequences encoding Interleukin-5), and ATCC No. 67153 (which contains sequences
30 encoding Interleukin-6).

Gene delivery vehicles expressing the above cytokines are useful in the treatment of a variety of disorders. For example, see PCT publication number

US94/02951 entitled "Compositions and Methods for Cancer Immunotherapy" for a description of gene therapy treatment of malignancy.

15. Neurological Disorders and Diseases

For stroke or any acute brain injuries, polynucleotides encoding tyrosine hydroxylase can be useful in treating
5 Parkinson disease.

For stroke or any acute brain injuries, polynucleotides encoding IGF-1, bFGF, vascular endothelial growth factor (VEGF) are useful.

16. Pulmonary Disorders

For treating emphysema, polynucleotides encoding $\alpha 1$ -anti-trypsin are
10 useful.

For treating lung fibrosis, polynucleotides encoding superoxide dismutase (SOD) are useful.

For treating cystic fibrosis, polynucleotides encoding CFTR are useful.

15 ADDITIONAL AGENTS

Additional agents can be included with the desired polynucleotides to be delivered. These additional agents can facilitate endocytosis of the desired nucleic acids or aid binding of the nucleic acids to the cell surface or both, for example.

20 A. Polypeptides

One example are polypeptides which include, without limitation:
asialoorosomucoid (ASOR); transferrin; asialoglycoproteins; antibodies;
antibody fragments; ferritin; interleukins; interferons, granulocyte, macrophage
25 colony stimulating factor (GM-CSF), granulocyte colony stimulating factor (G-CSF), macrophage colony stimulating factor (M-CSF), stem cell factor and erythropoietin. Viral antigens, such as envelope proteins, can also be used.
Also, proteins from other invasive organisms, such as the 17 amino acid peptide from the circumsporozoite protein of plasmodium falciparum known as RII.

B. Hormones, Vitamins, Etc.

Other groups that can be included are, for example: hormones, steroids, androgens, estrogens, thyroid hormone, or vitamins, folic acid.

C. Polyalkylenes, Polysaccharides, Etc.

5 Polyalkylene glycols can be included with the desired polynucleotides.

In a preferred embodiment, the polyalkylene glycol is polyethylene glycol. In addition, mono-, di-, or polysaccharides can be included. In a preferred embodiment of this aspect, the polysaccharide is dextran or DEAE-dextran.

Also, chitosan and poly(lactide-co-glycolide)

10 D. Lipids and Liposomes

The desired polynucleotide can also be encapsulated in lipids or packaged in liposomes prior to delivery to the subject or to cells derived therefrom.

Lipid encapsulation is generally accomplished using liposomes which are able to stably bind or entrap and retain nucleic acid. The ratio of condensed 15 polynucleotide to lipid preparation can vary but will generally be around 1:1 (mg DNA:micromoles lipid), or more of lipid. For a review of the use of liposomes as carriers for delivery of nucleic acids, see, Hug and Sleight, 1991, Biochim. Biophys. Acta, 1097:1-17; Straubinger *et al.*, in METHODS OF ENZYMOLOGY (1983), Vol. 101, pp. 512-527.

20 Liposomal preparations for use in the instant invention include cationic (positively charged), anionic (negatively charged) and neutral preparations.

Cationic liposomes have been shown to mediate intracellular delivery of plasmid DNA (Felgner *et al.*, 1987, Proc. Natl. Acad. Sci. USA 84:7413-7416); mRNA (Malone *et al.*, 1989, Proc. Natl. Acad. Sci. USA 86:6077-6081); and purified 25 transcription factors (Debs *et al.*, 1990, J. Biol. Chem. 265:10189-10192), in functional form.

Cationic liposomes are readily available. For example, N[1-2,3-dioleyloxy]propyl]-N,N,N-triethylammonium (DOTMA) liposomes are available under the product line Lipofectin®, from GIBCO BRL, Grand Island, NY. (See, 30 also, Felgner *et al.*, 1987, Proc. Natl. Acad. Sci. USA 84:7413-7416). Other commercially available liposomes include transfectace (DDAB/DOPE) and

DOTAP/DOPE (Boerhinger). Other cationic liposomes can be prepared from readily available materials using techniques well known in the art. See, e.g., Szoka *et al.*, 1978, *Proc. Natl. Acad. Sci. USA* 75:4194-4198; PCT Publication No. WO 90/11092 for a description of the synthesis of DOTAP (1,2-bis(oleoyloxy)-3-(trimethylammonio)propane) liposomes.

Similarly, anionic and neutral liposomes are readily available, such as from Avanti Polar Lipids (Birmingham, AL), or can be easily prepared using readily available materials. Such materials include phosphatidyl choline, cholesterol, phosphatidyl ethanolamine, dioleoylphosphatidyl choline (DOPC),
10 dioleoylphosphatidyl glycerol (DOPG), dioleoylphosphatidyl ethanolamine (DOPE), among others. These materials can also be mixed with the DOTMA and DOTAP starting materials in appropriate ratios. Methods for making liposomes using these materials are well known in the art.

The liposomes can comprise multilamellar vesicles (MLVs), small
15 unilamellar vesicles (SUVs), or large unilamellar vesicles (LUVs). The various liposome-nucleic acid complexes are prepared using methods known in the art. See, e.g., Straubinger *et al.*, in METHODS OF IMMUNOLOGY (1983), Vol. 101, pp. 512-527; Szoka *et al.*, 1978, *Proc. Natl. Acad. Sci. USA* 75:4194-4198;
1975, *Biochim. Biophys. Acta* 394:483; Wilson *et al.*,
20 1979, *Cell* 17:77; Deamer and Bangham, 1976, *Biochim. Biophys. Acta* 443:629; Ostro *et al.*, 1977, *Biochem. Biophys. Res. Commun.* 76:836; Fraley *et al.*, 1979, *Proc. Natl. Acad. Sci. USA* 76:3348); Enoch and Strittmatter, 1979,
1979, *Proc. Natl. Acad. Sci. USA* 76:145); Fraley *et al.*, 1980, *J. Biol. Chem.* 255:10431; Szoka and Papahadjopoulos, 1978, *Proc. Natl. Acad. Sci. USA* 75:145; and Schaefer-Ridder *et al.*, 1982, *Science* 215:166.

E. Lipoproteins

In addition, lipoproteins can be included with the polynucleotide to be delivered. Examples of lipoproteins to be utilized include: chylomicrons, HDL, IDL, LDL, and VLDL. Mutants, fragments, or fusions of these proteins can also
30 be used. Also, modifications of naturally occurring lipoproteins can be used, such as acetylated LDL. These lipoproteins can target the delivery of polynucleotides to cells expressing lipoprotein receptors. Preferably, if

lipoproteins are including with the polynucleotide to be delivered, no other targeting ligand is included in the composition.

If lipoproteins are included with the desired polynucleotides to be delivered, preferably, the composition comprises: (1) lipoprotein; (2) 5 polynucleotide; and (3) a polynucleotide binding molecule.

Naturally occurring lipoproteins comprise a lipid and a protein portion.

The protein portion are known as apoproteins. At the present, apoproteins A, B, C, D, and E have been isolated and identified. At least two of these contain several proteins, designated by Roman numerals, AI, AII, AIV; CI, CII, CIII.

10 A lipoprotein can comprise more than one apoprotein. For example, naturally occurring chylomicrons comprise A, B, C, and E, over time these lipoproteins lose A and acquire C and E apoproteins. VLDL comprises A, B, C, and E apoproteins, LDL comprises apoprotein B; and HDL comprises apoproteins A, C, and E.

15 The amino acids of these apoproteins are known and are described in, for example, Breslow, 1985, Annu Rev. Biochem 54:699; Law et al., 1986, Adv. Exp Med. Biol. 151:162; Chen et al., 1986, J. Biol. Chem. 261: 12918; Kane et al., 1980, Proc Natl Acad Sci USA 77:2465; and Utermann et al., 1984, Hum Genet 65:232.

20 Lipoproteins contain a variety of lipids including, triglycerides, cholesterol (free and esters), and phospholipids. The composition of the lipids varies in naturally occurring lipoproteins. For example, chylomicrons comprise mainly triglycerides. A more detailed description of the lipid content of naturally occurring lipoproteins can be found, for example, in Meth. Enzym. 128 25 (1986). The composition of the lipids are chosen to aid in conformation of the apoprotein for receptor binding activity. The composition of lipids can also be chosen to facilitate hydrophobic interaction and association with the polynucleotide binding molecule.

Naturally occurring lipoproteins can be isolated from serum by 30 ultracentrifugation, for instance. Such methods are described in Meth. Enzy., supra; Pitas et al., 1980, J. Biochem. 255:5454-5460; and Mahey et al., 1979, J. Clin. Invest. 64:743-750.

Lipoproteins can also be produced by *in vitro* or recombinant methods by expression of the apoprotein genes in a desired host cell. See, for example, Atkinson *et al.*, 1986, Annu Rev Biophys Chem 15:403, and Radding *et al.*, 1958, Biochim. Biophys Acta 30:443.

5 Lipoproteins can also be purchased from commercial suppliers, such as Biomedical Technologies, Inc., Stoughton, Massachusetts, USA.

Mutants, fragments and fusion of the naturally occurring apoproteins are useful for delivery of polynucleotides. These polypeptides will retain more than about 80% amino acid identity; more typically, more than about 85%; even more 10 typically, at least 90%. Preferably, these polypeptides will exhibit more than about 92% amino acid sequence identity with naturally occurring lipoproteins or fragment thereof; more preferably, more than about 94%; even more preferably, more than about 96%; even more preferably, more than about 98%; even more preferably, more than about 99% sequence identity.

15 Such mutants, fragments and fusions can be constructed by altering the polynucleotides encoding the desired lipoproteins by recombinant DNA techniques. See, for example, Sambrook *et al.*, (1989) Molecular Cloning, A Laboratory Manual, 2d edition (Cold Spring Harbor Press, Cold Spring Harbor, New York). These polynucleotides can be inserted into expression vectors and 20 host cells can be utilized to produce the desired apoprotein.

In addition, naturally occurring lipoproteins, mutants, fragments, and fusions can be chemically altered. For example, acetylated LDL has biological activity. See, for example, Nagelkerke *et al.*, 1983, J. Biol. Chem. 258(20):12221-12227; Weisgraber *et al.*, 1978, J. Biol. Chem. 253:9053-9062; 25 Voyta *et al.*, 1984, J. Cell Biol. 99:2034-2040; Goldstein *et al.*, 1979, Proc. Natl. Acad. Sci. USA 76:333-337; and Pitas, 1981, Arterosclerosis 1:177-185.

Chemically modified lipoproteins can also be purchased from commercial suppliers, such as Biomedical Technologies, Inc., Stoughton, Massachusetts, USA.

30 All of these polypeptides exhibit receptor binding properties of naturally occurring lipoproteins. Usually, such polypeptides exhibit at least about 20% receptor binding of naturally occurring lipoproteins. More typically, the polypeptides exhibit at least about 40%, even more typically the polypeptides

exhibit at least about 60%; even more typically, at least about 70%; even more typically, at least about 80%; even more typically, at least about 85%; even more typically, at least about 90%; even more typically, at least about 95% receptor binding of the naturally occurring lipoproteins.

5 Typically, lipoproteins are present in an amount effective to increase the frequency of incorporation of polynucleotides into a cell. Such an amount is sufficient to increase the frequency of incorporation of polynucleotides into a cell by at least 10%, compared to the frequency of incorporation of naked polynucleotides; more usually, at least 15%; even more usually, 20%; even more 10 usually, at least 30%. The increase can be between 40 to 100%, and even 1000% and 10000% increase.

"Polynucleotide binding molecule" refers to those compounds that associate with polynucleotides, and the association is not sequence specific. For example, such molecules can (1) aid in neutralizing the electrical charge of 15 polynucleotide, or (2) facilitate condensation of nucleotides, or (3) inhibit serum or nuclease degradation. Optionally, polynucleotide binding molecules can interact with lipoproteins by either hydrophobic association or by charge. Polynucleotide binding molecules include, without limitation, polypeptides, mineral compounds, vitamins, etc.

20 Examples of polynucleotide binding molecules include: polylysine, polyarginine, polyornithine, and protamine. Examples of organic polycations include: spermine, spermidine, and putrescine. Other examples include histones, protamines, human serum albumin, DNA binding proteins, non-histone chromosomal proteins, coat proteins from DNA viruses, such as ϕ X174, 25 transcriptional factors also contain domains that bind DNA and therefore may be useful as nucleic acid condensing agents. Briefly, transcriptional factors such as C/CEBP, c-jun, c-fos, AP-1, AP-2, AP-3, CPF, Prot-1, Sp-1, Oct-1, Oct-2, CREP, and TFIID contain basic domains that bind DNA sequences.

30 Examples of other positively charged moieties include polybrene, DEAE-dextran, and cationic lipids. Useful cationic lipids and liposomes are described above. Lipids and liposomes are not used in this aspect of the invention to encapsulate both polynucleotide and lipoprotein. The lipoprotein must be exposed to bind its cell surface receptor.

Other synthetic compounds that are capable of binding negatively charged polynucleotides are useful, such as polymers of N-substituted glycines and others, as described below.

In a composition with a lipoprotein, the polynucleotide binding molecule 5 can be present in an amount effective to neutralize the polynucleotide. However, the polynucleotide binding molecule also can be in excess of an effective amount to neutralize the polynucleotide to be delivered. Such an excess can produce a net positive electrical charge when complexed with the polynucleotides to be delivered. The positively charged complex can then interact with lipoproteins 10 that comprise negatively charged lipids, such as phospholipids.

Typically, the polynucleotide binding molecule is in excess when the amount is 10% greater than the amount to neutralize the polynucleotide charge; more typically, the amount is 50% greater; even more typically, 100% greater; even more typically, 150% greater; even more typically, 200% greater; even 15 more typically, 500% greater; even more typically, 20,000% greater; even more typically, 22,000% greater; even more typically, 25,000% greater; even more typically, 30,000% greater; even more typically, more than 40,000% greater than the amount effective to neutralize the electrical charge of the desired polynucleotide.

20 **POLYCATIONIC AGENTS**

Polycationic agents can be included, with or without lipoprotein, in a composition with the desired polynucleotide to be delivered.

Functional properties

A. Net Positive Charge

25 Polycationic agents typically exhibit a net positive charge at physiological relevant pH and are capable of neutralizing the electrical charge of nucleic acids to facilitate delivery to a desired location. These agents have both *in vitro*, *ex vivo*, and *in vivo* applications. For example, these polycationic agents can be used to transfect cells used to produce recombinant proteins.

30 Alternatively, the instant polycationic agents can be used to deliver nucleic acids to a living subject either intramuscularly, subcutaneously, etc.

Physiological relevant pH varies somewhat between *in vitro* and *in vivo* applications. Typically, physiological pH is at least 5.5; more typically, at least 6.0; even more typically, at least 6.5. Usually, physiologically relevant pH is no more than 8.5; more usually, no more than 8.0; even more usually, no more than 5 7.5.

Preferably, the isoelectric point of the instant polycationic agents to neutralize nucleic acids is at least 9.

B. Non-Toxicity and Non-Immunogenic Properties

The composition of the polycationic agents of the invention will exhibit 10 the toxicity and immunogenic properties desired. *In vitro* cell culture will have different immunogenic constraints than *in vivo* mammalian applications.

The instant polycationic agents can be easily tested for toxicity. For example, the agents can be added to medium for cells used in the *in vitro* assays, such as cos-7, Chinese Hamster Ovary cells, etc. Alternatively, the agents can be 15 tested in standard animal tests for safety.

C. Condensation Properties

Due to the electric charge, a subset of these polycationic agents are capable of condensing the desired nucleic acids to a compact size to facilitate delivery. Typically, condensation "collapses" polynucleotides or nucleic acids 20 into macromolecular structures, commonly into a toroid form. The smaller size of condensed nucleic acids eases delivery by facilitating, for example, packaging nucleic acids into liposomes and/or reducing exposure to proteases and/or nucleases.

The condensed nucleic acids exhibit different properties compared to 25 "relaxed" nucleic acids, such as (1) a decrease in intercalation of ethidium bromide or other intercalating dye or (2) a reduced mobility in gel electrophoresis. Thus, condensation can be measured by at least two different assays, an intercalating dye assay or a band shift assay.

One type of intercalating dye assay uses ethidium bromide. In this assay, 30 test nucleic acids, conveniently plasmid DNA, are mixed with polycationic agent in a ratio from about 1:1 to a 1:50 weight/weight ration of plasmid to condensing

agent. Following incubation, ethidium bromide is added to the reaction to a final concentration of 1 µg/mL. If a nucleic acid such as RNA is used as the test nucleic acid, acridine orange may be used as the intercalating dye. The reaction mixtures are transferred into UV transparent plastic tubes spotted with 1% agarose gel, or placed upon UV transparent plastic c and illuminated with 260 nm light. The emission from the DNA-ethidium bromide complex is recorded on film by a camera equipped with an appropriate UV filter. The ability of an agent to condense DNA is inversely proportional to the intensity of the fluorescence in each reaction mixture.

10 The more precise test is a band shift assay. Briefly, this assay is performed by incubating nucleic acids, either labeled or unlabeled, with various concentrations of candidate condensing agents. Test nucleic acids, conveniently plasmid DNA, and condensing agent are mixed at 1:1 to 1:50 w/w ratios. Following incubation, each sample is loaded on a 1% agarose gel and 15 electrophoresed. the gel is then either stained with ethidium bromide or dried and autoradiographed. DNA condensation is determined by the inability to enter the gel compared to a non-condensed standard. Sufficient condensation is achieved when at least 90% of the DNA fails to enter the gel to any significant degree.

20 Condensation can also be measure by directly determining the size of the complex using a light scattering instrument such as the a Coulter N4MD submicron analyzer, for example. Polynucleotides and a condensing agent are incubated at an appropriate ratio, either alone or in the present of 2% PEG-2000 (Fisher Scientific), and 0.6 M NaCl., and then diluted into 3 ml of water. This 25 dilute solution is analyzed by the Coulter counter which will detect particles with a mean size of 0-1,000 nanometers (nm). Condensing agents, such as poly-L-lysine, typically yield particles with a mean diameter of approximately 50-200 nm. See Lee *et al.*, 1996, *J. Biol. Chem.* 271: 8481-8487.

D. Serum and/or Nuclease Protection Properties

30 The instant polycationic agents are capable of protecting nucleic acids from degradation in serum or from nucleases, including nucleases present in biological fluids, such as serum, prostate, synovial fluid, etc. One advantage of

this type of protection is that smaller amounts of the desired nucleic acids are needed for efficient administration.

When present in effective amounts, these polycationic agents can inhibit serum degradation by at least 5 minutes as compared with uncomplexed nucleic acids; more usually, the amount used is sufficient to inhibit degradation by at least 10 minutes; even more usually, the amount used is sufficient to inhibit degradation by at least 30 minutes; even more usually, the amount used is sufficient to inhibit degradation by at least 45 minutes; even more usually, the amount used is sufficient to inhibit degradation by at least 60 minutes; even more usually, the amount used is sufficient to inhibit degradation by at least 90 minutes; and more usually, the amount used is sufficient to inhibit degradation by at least 120 minutes.

Increased serum protection can be measured simply by incubation of the polycation/polynucleotide complex with mouse serum, for example. Preferably, the serum will not be heat inactivated. After incubation, the mixture can be analyzed by gel electrophoresis to determine the quantity of the polynucleotides remaining after incubation.

Alternatively, nucleases can be added to the polycationic agent/nucleic acid complexes. The resulting mixture can be analyzed by gel electrophoresis to determine the amount of degradation. Other biological fluids, such as prostate fluid, can also be tested.

E. Mediating Entry of Polynucleotides into a Cell

The polycationic agents can mediate entry of polynucleotides into a cell. Incorporation of polynucleotides into a cell can be measured by either protein expression assays or polynucleotide hybridization techniques, for example.

One method of detecting frequency of incorporation is to include a gene that encodes a marker protein, such as luciferase. Cells that have incorporated the delivered polynucleotides will express the marker protein. The protein can be detected by standard immunoassays, or by biological or enzymatic activity, as in the case of luciferase.

Alternatively, standard hybridization techniques, such as Southern or Northern blots or polymerase chain reaction (PCR) techniques, can be used to detect the presence of the desired polynucleotides.

F. Additional Properties

5 To facilitate entry of nucleic acids to the interior of cells, the instant agents can be capable of

- (a) binding the polynucleotide to the cell surface;
- (b) cell membrane destabilization;
- (c) triggering endocytosis;
- 10 (d) endosome buffering capacity;
- (e) releasing DNA/lipid complexes from endosomes; or
- (f) nuclear tropism.

Assays for detecting these characteristics are standard and known to those skilled in the art.

15 Physical Properties

The following physical characteristics are factors to consider when determining the composition of the polycationic agents:

- (a) distance between the substituents and the backbone
- (b) the total length of the chain;
- 20 (b) hydrophobicity and/or aromacity;
- (c) number of hydrogen bonding groups; and
- (c) charge, including
 - (i) type of charge group, (ii) density of charge and (iii) position.

Other relevant characteristics include structural flexibility. For example, a
25 helical conformation of the polycationic agent may be preferred for some applications.

Specific dimensions to be considered include

- (a) the distance of phosphate groups in the polynucleotide of interest; and
- (b) the distance of monomer groups in the agents of interest.

Polypeptide Polycationic Agents

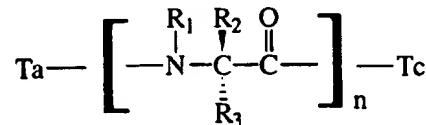

The following are examples of useful polypeptides as polycationic agents: polylysine, polyarginine, polyornithine, and protamine. Other examples include histones, protamines, human serum albumin, DNA binding proteins, 5 non-histone chromosomal proteins, coat proteins from DNA viruses, such as φX174, transcriptional factors also contain domains that bind DNA and therefore may be useful as nucleic acid condensing agents. Briefly, transcriptional factors such as C/CEBP, c-jun, c-fos, AP-1, AP-2, AP-3, CPF, Prot-1, Sp-1, Oct-1, Oct-10 2, CREP, and TFIID contain basic domains that bind DNA sequences.

The dimensions and of the physical properties of a polycationic agent can be extrapolated from the list above, to construct other polypeptide polycationic agents or to produce synthetic polycationic agents.

15 Synthetic Polycationic Agents

Synthetic polycationic agents which are useful include, for example, DEAE-dextran, polybrene. Lipofectin®, and lipofectAMINE™ are monomers that form polycationic complexes when combined with polynucleotides.

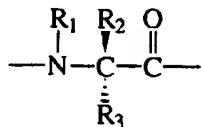

A preferred group of polycationic agents of the present invention have the following general formula (I):

A preferred subset of these compounds include compounds having formula (I) where R₁ is hydrogen. Even more preferred are polymers comprising at least one natural amino acid. Also preferred are polymers where R₂ and R₃ are both hydrogen, also referred to as poly N-substituted glycines or poly NSGs.

A. Monomers

The polycationic agent of the invention comprises monomers with the following structure (II):

Generally, R₁, R₂, and R₃ are moieties each with a molecular weight from 1 to 250 daltons. More typically, the molecular weight is no more than 200; even more typically, no more than 175.

- 5 Typically, each monomer comprises one hydrogen at R₁, R₂, or R₃. More typically, either R₁ and R₂ are both hydrogen, the structure of an L-amino acid; or R₂ and R₃ are both hydrogen, the structure of a NSG.

Monomers to be utilized in the polycationic agents can be either positively or negatively charged. Also, neutral substituents can also be utilized.

- 10 Degradation sites can be incorporated into the polymer, for example, by including substituents from a natural amino acid when R_1 and R_2 are hydrogen. These monomers can be positively or negatively charged, or neutral.

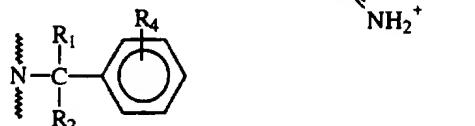

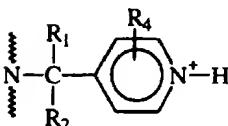

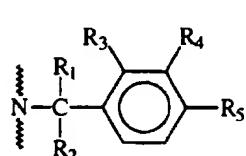

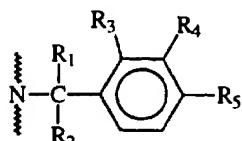

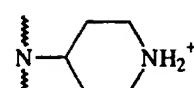

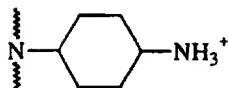

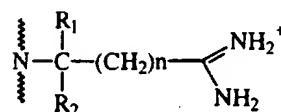

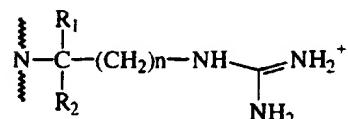

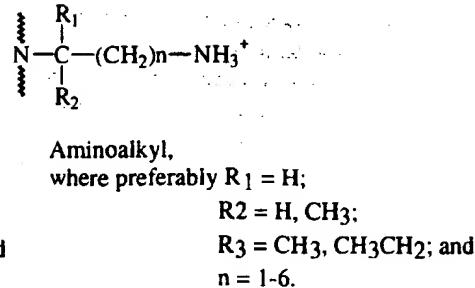

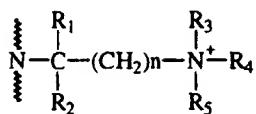

As a general rule, a basically charged monomer has a pKa value for the side chain of at least 7.5. Positively, or basically, charged monomers include without limitation those containing the following functional groups: amino, guanidino, hydrazido, and amidino. These functional groups can be either aromatic or aliphatic.

- Positively charged monomers comprising hydrogen at R₁ and R_{1'}, can be included in the polycationic agent, for example, as a degradation site. Such degradation site may aid in separation of the polycationic agent from the polynucleotide to permit further processing. For an L-amino acid like monomer, useful R₁ substitutents are, for example, from those found in naturally occurring amino acids, such as lysine and arginine. Also, sidechains from amino acid analogues can be used such as ornithine and canaline; or modifications of basic amino acids, such as homoarginine, and modifications of other amino acids such as guanidinovalinate, and aminoethylcysteine. The substitutents found in L-

amino acids can also be incorporated at the R₁ and R₂ positions of the instant polycationic agents.

Naturally occurring amino acids and analogues are designated D-amino acids to indicate the chirality of these molecules. L-amino acids can also 5 incorporate as monomers into the polycationic agents. The substituents of L-amino acids can be, for example, the same as those named for the D-amino acids.

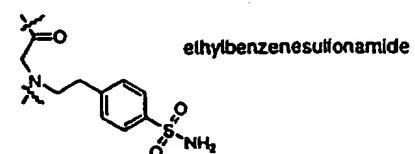

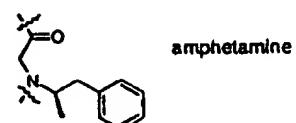

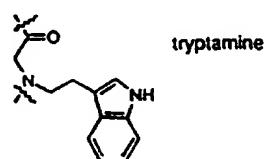

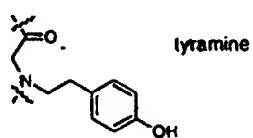

Preferable monomers include N-substituted glycine monomers. Exemplary N-substitutions include alkylphenyl, indolylalkyl, alkoxyphenyl, halophenylalkyl, hydroxyphenylalkyl, as well as the N-substitutions shown below.

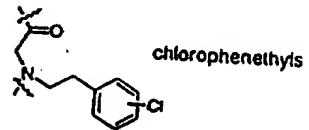

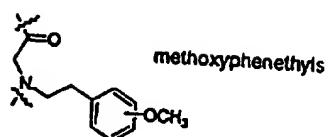

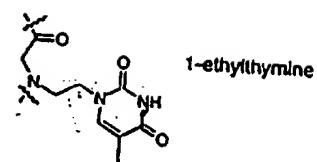

The positively charged substituents described above can also be placed at the R₁ or R₂ positions of formulas (I) and (II).

The polycationic agents can comprise negatively charged or neutral monomers. As with the positively charged monomers, D-amino acid, L-amino acid, and NSGs are preferred to be incorporated as monomers.

The following are examples of such monomers:

B. Polycationic Polymers

Typically, the polycationic agents exhibit a predicted isoelectric point of at least 5 9, excluding the terminal groups. Further, the agents contain, excluding the terminal groups, at least 20% positively charged monomers; more typically, at least 25%; more typically, 30%; and preferably, at least 33% positively charged monomers. Typically, the agents do not comprises greater than 5% acidic monomers and preferably none.

10 The charge density and composition of the polycationic agent can be altered to accommodate the specific nucleic acid sequence, type, and other components included with the complex of nucleic acids and polycationic agent.

Usually, the length of the polymer is at least 8 monomers; even more usually, 12 monomers; even more usually, 18 monomers. More typically, the polycationic agents of the invention will be at least 24 monomer units in length; more typically, 30 monomer 15 units; even more typically, 36 monomer units; even more typically, 48 monomer units. The polycationic agent can be up to 50 to 75 to 100 monomer units in length.

Preferably, the polycationic agent comprises monomers where all R₂ and R₃ are hydrogen. Even more preferably, where all R₂ and R₃ are hydrogen, the polycationic agent comprise repeating trimer units with the following monomer sequence (from amino 20 to carboxy terminus): (1) neutral monomer, (2) neutral monomer, and (3) positively charged monomer.

Preferably, the neutral monomer comprises an aromatic group at the R₁ position; more preferably, wherein the aromatic group comprises a single ring; even more preferably, wherein the aromatic group is a six member ring.

25 Typically, the positively charged monomer is aminoalkyl at the R₁ position; more typically, the aminoalkyl comprises 1-6 carbon molecules; even more typically, the aminoalkyl is aminoethyl.

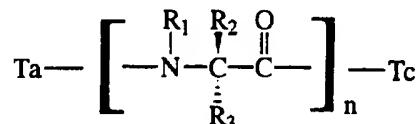

Typically, the polycationic agent comprises between 3 to 20 repeating trimers, trimers having two neutral and one positively charged R₁ groups are preferred, such as, 30 for example, trimer shaving the sequence, neutral monomer, neutral monomer, positively charged monomer. More preferably, the polycationic agent comprises 5 to 18 trimers; preferably 8 to 16 trimers; and even more preferably, 12 to 16 trimers.

Optionally, the polycationic agent contains only positively charged monomers, excluding the terminal groups. Typically, such a polycationic agent comprises between 24 and 48 monomers; more typically, 30 to 40 monomers; even more typically, 36 monomers.

5 Polycationic agents of the present invention containing only positively charged monomers typically have guanidinoalkyl sidechains. Typically, the guanidinoalkyl sidechain comprises 1 to 6 carbon molecules. Preferably, the side chain is guanidino ethyl.

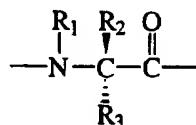

C. Neutral Polymers

10 A preferred group of neutral polymers of the present invention have the general formula (I):

Preferably, R₂ is hydrogen. Even more preferred are polymers comprising at least one natural amino acid. Also preferred are polymers having formula (I) where R₂ and R₃ are hydrogen, also referred to as poly N-substituted glycines or poly NSGs.

Monomers employed in neutral polymers of the present invention have the same general formula as monomers employed in cationic polymers of the present invention, i.e.:

Generally, R₁, R₂, and R₃ are moieties each with a molecular weight from 20 to 250 daltons. More typically, the molecular weight is no more than 200; even more typically, no more than 175.

Typically, each monomer comprises one hydrogen at R₁, R₂, or R₃. More typically, either R₁ and R₃ are both hydrogen, the structure of a L-amino acid; or R₂ and R₃ are both hydrogen, the structure of a NSG.

Monomers to be utilized in the neutral agents can be either positively or negatively charged. Also, neutral substituents can also be utilized. Neutral polymers exhibit no net positive or negative charge, excluding the terminal groups.

- 5 Degradation sites can be incorporated into the polymers by using naturally occurring amino acid substituents in monomers when R₁ and R₂ are hydrogen.

- Naturally occurring amino acids and analogues are designated D-amino acids to indicate the chirality of these molecules. L-amino acids can also 10 incorporate as monomers into the neutral polymers. The substituents of L-amino acids can be, for example, the same as those named for the D-amino acids.

Preferred monomers include N-substituted glycine monomers, and monomers that are capable of forming hydrogen bonds and/or ionic bonds with the polynucleotides to be delivered.

- 15 Examples of monomers for the neutral polymers include those described above and in the Examples below.

D. Linking Polymers Together

- Polymers can be linked together incorporating terminating groups or sidechains that permit cross-linking of the polymers. For example, polymers can 20 be linked by a disulfide bond. Other terminating groups useful for coupling polymers include, carbonate, urea, and the like.

E. Additional Groups to be Incorporated into the Polymer

- Additional components can be included in the polycationic agents of the instant invention, such as targeting ligands. Such additional groups can facilitate 25 endocytosis of the desired nucleic acids or aid binding of the nucleic acids to the cell surface.

- Polypeptides can be incorporated into the polycationic agents. Examples include, without limitation: asialoorosomucoid (ASOR); transferrin; asialoglycoproteins; antibodies; antibody fragments; ferritin; interleukins; 30 interferons, granulocyte, macrophage colony stimulating factor (GM-CSF), granulocyte colony stimulating factor (G-CSF), macrophage colony stimulating

factor (M-CSF), stem cell factor and erythropoietin. Viral antigens, such as envelope proteins, can also be used. Also, proteins from other invasive organisms are useful, such as the 17 amino acid peptide from the circumsporozoite protein of plasmodium falciparum known as RII.

5 In addition, lipoproteins can be incorporated into the polycationic agent, such as low density lipoprotein, high density lipoprotein, or very low density lipoprotein. Mutants, fragments, or fusions of these proteins can also be used.

Other groups that can be incorporated include without limitation: hormones, steroids, androgens, estrogens, thyroid hormone, or vitamins, folic acid. Folic acid can be incorporated into the polycationic agent according, for example, to Mislick *et al.*, 1995, *T.J. Bioconjugate Chem.* 6:512.

10 Also, the polycationic agents of the instant invention can be chemically conjugated with polyalkylene glycol. In a preferred embodiment, the polyalkylene glycol is polyethylene glycol. PEG can be incorporated with a 15 polycation agent according, for example, to Lu *et al.*, 1994, *Int. J. Pept. Protein Res.* 43:127.

In addition, the polycationic agent can be chemically conjugated with mono-, di-, or polysaccharide. In a preferred embodiment of this aspect, the polysaccharide is dextran.

20 These additional groups can be incorporated within the polycationic agent. For example, R₁, R₂, and R₃ can be a substituent that is capable of being activated to cross link with any one of the above groups. For example, a thiol group could be included to cross link with another group to form a disulfide bond.

25 **F. Terminal Groups**

The terminal groups of the instant polycationic agents can be chosen as convenient. Suitable terminal groups (i.e., Ta and Tc) include, for example, -NH₂, -OH, -SH, and -COOH. Terminal groups can be selected to enhance the targeting properties of the polycationic agent and can be any of the additional 30 groups described above.

The additional groups described above can be incorporated at the terminus of the polycationic agent. For example, the polycationic agent can be

(1) acylated with a variety of carboxylic acids; (2) sulfonylated with sulfonyl chlorides; or (3) derivatized with isocyanates or isothiocyanates. Once activated, the terminus can be reacted with any of the above-mentioned groups, such as a polypeptide, such as low density lipoprotein, or folic acid.

5 One means of adding a terminal group to the polycationic agent is, for example, is (1) to acylate the amino terminus with Fmoc-amino-hexanoic acid; and (2) to remove the protecting group, Fmoc, to generate a primary amine, which can be further functionalized.

Alternatively, the amino-terminal groups can include, without limitation:
10 acyl, such as acetyl, benzoyl; or sulfonyl, such as dansyl.

Carboxy terminal groups can include, for example, amide or alkyl amide.

Synthesis of Polycationic Agents

Polycationic agents of the present invention can be synthesized by either solid or solution phase methods. The following is a solid phase method for the 15 synthesis of NSGs, which can be generally used for a wide variety of side-chain substitutents. This method can be performed utilizing automated peptide synthesis instrumentation to permit rapid synthesis of polycationic agents of interest. Such instruments are commercially available from, for example, Applied Biosystems and Milligen.

20 A. Two Step Monomer Assembly

A method of synthesis is to assemble the monomer from two submonomers in the course of extending a polymer comprising an NSG monomer. This technique is described in Zuckermann *et al.*, 1992, *J Amer Chem Soc* 114(26):10646-10647, and Zuckermann *et al.*, PCT Patent Publication No.

25 WO 94/06451. The NSGs can also be considered to be an alternating condensation copolymer of an acylating agent and an amine.

The direction of polymer synthesis with the submonomers occurs in the carboxy to amino direction. The solid-phase assembly for each monomer, in the course of polymer formation, eliminates the need for N α -protected monomers, as 30 only reactive side-chain functionalities need to be protected.

Each monomer addition comprises two steps, an acylation step and a nucleophilic displacement step as shown in Figure 1.

Specifically, each cycle of monomer addition consists of two steps:

- (1) acylation of a secondary amine bound to the support with an acylating agent comprising a leaving group capable of nucleophilic displacement by an amine and a carbonyl group, preferably carboxyl. An example is a haloacetic acid; and
- 5 (2) nucleophilic displacement of the leaving group with a sufficient amount of a submonomer comprising a primary amino group to introduce a side-chain. The amino group containing submonomer can be an alkoxyamine, 10 semicarbazide, acyl hydrazide, substituted hydrazine or the like.

Acylation can be activated with carbodiimide or other suitable carboxylate activation method.

The efficiency of the displacement is modulated by the choice of halide, 15 e.g., I>Cl. Protection of aliphatic hydroxyl groups, carboxylic acids, carboxy, thiol, amino, some heterocycles, and other reactive side-chain functionalities is preferred to minimize undesired side reactions. However, the mild reactivity of some side-chain moieties toward displacement or acylation may allow their use without protection., e.g., indole, imidazole, and phenol.

20 B. Three Step Monomer Assembly

NSGs can also be constructed utilizing a three step method for assembling each monomer as the polymer is extended. The backbone of the monomer is first extended by acylation step followed by a nucleophilic displacement. The side chain is introduced by a second acylation step. The reaction scheme is shown in Figure 2.

The backbone of the monomer is assembled in the first two steps of the synthesis cycle. The first reaction is an acylation step where the carbonyl group of the acylating agent reacts with an amine. The acylating agent comprises a carbonyl group; a backbone, R₁; and a leaving group, L. Preferably, the carbonyl group is carboxyl.
25

The second step is a nucleophilic displacement of the leaving group by the first amino group of the displacing agent. The displacing agent comprises a

first and a second amino group and a backbone, R_d. The first amino group is a primary amine, and the second step produces a secondary amine.

The third step is another acylation in which the another acylating submonomer reacts with the first amino group of the displacing agent to produce
5 a tertiary amide. The acylation agent comprises a carbonyl group; an optional linker; and a sidechain. Preferably, the carbonyl group is carboxyl.

Pharmaceutical Compositions

The polycationic agent/polynucleotide complexes, whether or not encapsulated in liposomes, may be administered in pharmaceutical compositions.

10 The pharmaceutical compositions comprise a therapeutically effective amount of nucleic acids.

The term "therapeutically effective amount" as used herein refers to an amount of a therapeutic agent sufficient to detectably treat, ameliorate, or prevent a particular disease or condition, i.e., an amount sufficient to induce a detectable
15 therapeutic or preventative effect. The effect may include, for example, chemical markers or antigen levels. Therapeutic effects also include reduction in physical symptoms, such as decreased body temperature. The precise effective amount for a subject will depend upon the subject's size and health, the nature and extent of the cardiovascular condition, and the therapeutics or combination of
20 therapeutics selected for administration. Thus, it is not useful to specify an exact effective amount in advance. However, the effective amount for a given situation can be determined by routine experimentation and is within the judgment of the clinician. For purposes of the present invention, an effective dose will be from about 0.01 mg/kg to 50 mg/kg or 0.05 mg/kg to about 10
25 mg/kg of the DNA constructs in the individual to which it is administered.

A pharmaceutical composition can also contain a pharmaceutically acceptable carrier. The term "pharmaceutically acceptable carrier" refers to a carrier for administration of a therapeutic agent, such as antibodies or a polypeptide, genes, and other therapeutic agents. The term refers to any
30 pharmaceutical carrier that does not itself induce the production of antibodies harmful to the individual receiving the composition, and which may be administered without undue toxicity. Suitable carriers may be large, slowly

metabolized macromolecules such as proteins, polysaccharides, polylactic acids, polyglycolic acids, polymeric amino acids, amino acid copolymers, and inactive virus particles. Such carriers are well known to those of ordinary skill in the art.

Pharmaceutically acceptable salts can be used therein, for example, 5 mineral acid salts such as hydrochlorides, hydrobromides, phosphates, sulfates, and the like; and the salts of organic acids such as acetates, propionates, malonates, benzoates, and the like. A thorough discussion of pharmaceutically acceptable excipients is available in *Remington's Pharmaceutical Sciences* (Mack Pub. Co., N.J. 1991).

10 Pharmaceutically acceptable carriers in therapeutic compositions may contain liquids such as water, saline, glycerol and ethanol. Additionally, auxiliary substances, such as wetting or emulsifying agents, pH buffering substances, and the like, may be present in such vehicles. Typically, the therapeutic compositions are prepared as injectables, either as liquid solutions or 15 suspensions; solid forms suitable for solution in, or suspension in, liquid vehicles prior to injection may also be prepared. Liposomes are included within the definition of a pharmaceutically acceptable carrier.

Delivery Methods

Once formulated, the compositions of the invention can be administered 20 (1) directly to the subject; (2) delivered *ex vivo*, to cells derived from the subject; or (3) *in vitro* for expression of recombinant proteins. The subjects to be treated can be mammals or birds. Also, human subjects can be treated.

Direct delivery of the compositions will generally be accomplished by 25 injection, either subcutaneously, intraperitoneally, intravenously or intramuscularly or delivered to the interstitial space of a tissue. The compositions can also be administered into a tumor or lesion. Other modes of administration include oral and pulmonary administration, suppositories, and transdermal applications, needles, and gene guns or hyposprays. Dosage treatment may be a single dose schedule or a multiple dose schedule.

30 Methods for the *ex vivo* delivery and reimplantation of transformed cells into a subject are known in the art and described in e.g., International Publication No. WO 93/14778 (published 5 August 1993). Examples of cells useful in *ex*

vivo applications include, for example, stem cells, particularly hematopoietic, lymph cells, macrophages, dendritic cells, or tumor cells.

Generally, delivery of nucleic acids for both *ex vivo* and *in vitro* applications can be accomplished by the following procedures, for example,

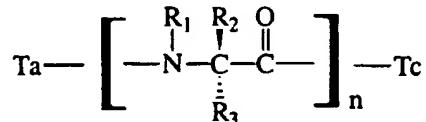

- 5 dextran-mediated transfection, calcium phosphate precipitation, polybrene mediated transfection, protoplast fusion, electroporation, encapsulation of the polynucleotide(s) in liposomes, and direct microinjection of the DNA into nuclei, all well known in the art.

The examples presented below are provided as a further guide to the practitioner of ordinary skill in the art, and are not to be construed as limiting the invention in any way.

Example 1

Synthesis of Polycationic Agents

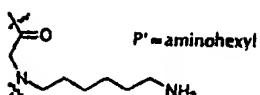

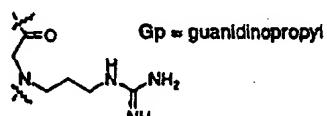

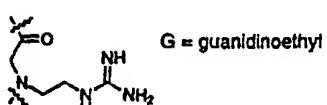

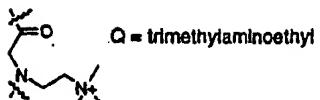

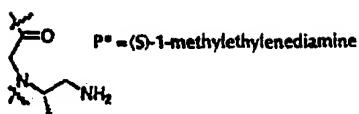

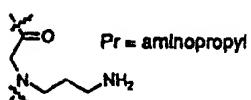

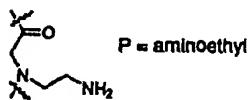

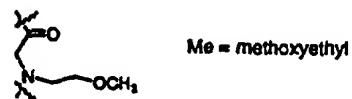

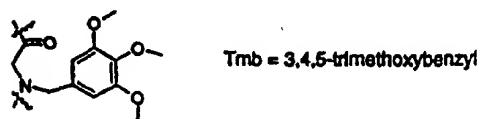

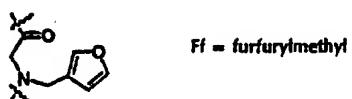

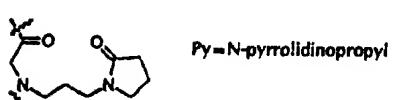

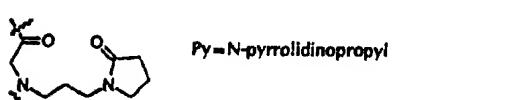

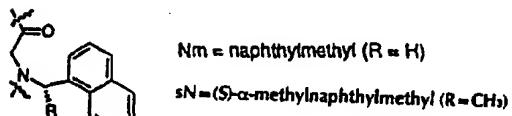

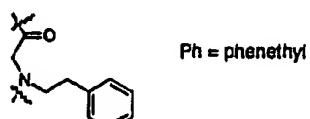

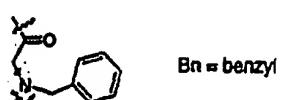

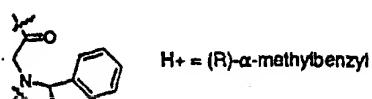

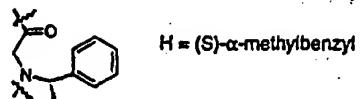

This example describes the synthesis of polycationic agents with the following structure:

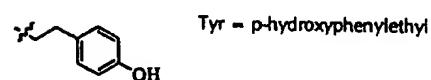

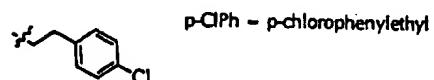

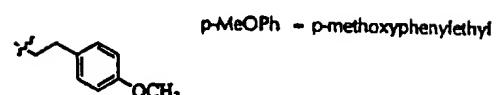

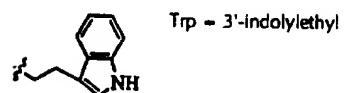

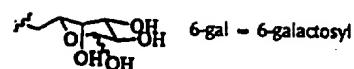

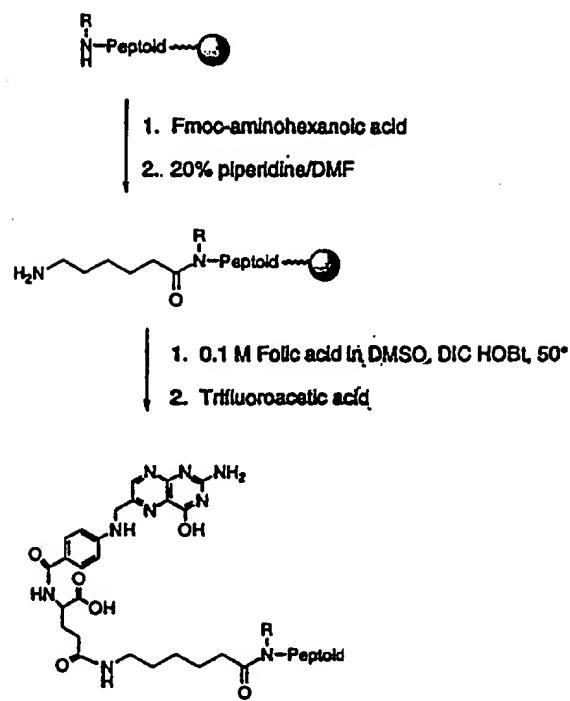

where R₁ and R₂ are hydrogen for all monomers. All polymers described in this example terminate in an amino and a carboxyl group unless specified, such as a folate terminating group.

The polycationic agents described below were synthesized according to
the procedures described in Figliozi *et al.*, 1996, *Meth. Enzy.* **267**:437-447, and
Zuckermann *et al.*, 1992, *J. Amer. Chem. Soc.* **114**(26):10646-10647.

All polymers were synthesized using bromoacetic acid and primary amines. The following are substituents of the primary amines to be positioned at R, to construct the polycationic agents:

*purified

To summarize the method, Fmoc-Rink amide resin (NovaBiochem, San Diego, California, USA) is used as the solid support. This is the same resin that is used for the Fmoc synthesis of peptide C-terminal amides. The polycationic synthesis begins with the deprotection of the Fmoc group on the resin with 20% (v/v) piperidine-dimethylformamide (DMF). The amino resin is then acylated with bromoacetic acid. This is followed by nucleophilic displacement of the bromide with a primary amine to build the NSG monomer. The latter two steps are then continued in an iterative fashion to elaborate the desired oligomer.

All reactions and washings were performed at room temperature unless otherwise noted. Washing of the resin refers to the addition of a wash solvent (usually DMF or dimethylsulfoxide (DMSO)) to the resin, agitating the resin so that a uniform slurry is obtained (typically for about 20 seconds), followed by thorough draining of the solvent from the resin. Solvents were removed by vacuum filtration through the fritted bottom of the reaction vessel until the resin appeared dry (typically about 5 seconds). In all the syntheses, resin slurries were agitated via bubbling argon up through the bottom of the fritted vessel.

A fritted reaction vessel was charged with 100 mg (50 µmol) of Fmoc-Rink amide resin with a substitution level ~ 0.50 mmol/g resin. Two milliliters of DMF was added to the resin and this solution was agitated for 1-2 minutes to swell the resin. The DMF was then drained. The Fmoc group was then removed by adding 2.0 ml of 20% piperidine in DMF to the resin. This was agitated for 1 minute and then drained. Another 2 ml of 20% piperidine in DMF was added to the resin and agitated for 15 minutes and then drained. The resin was then washed with DMF, six times with 2 ml.

The deblocked amine was then acylated by adding 850µl of 0.6 M bromoacetic acid in DMF to the resin followed by 200 µl of 3.2 M N,N'-

diisoprooplycarbodiimide (DIC) in DMF. This solution was agitated for 30 minutes at room temperature and then drained. This step was repeated a second time. The resin was then washed with DMF, twice with 2 ml and DMSO, once with 2 ml. This completed one reaction cycle.

5 The second cycle was initiated by the acylating step with bromoacetic acid and DIC, followed by displacement with the second amine. This acylation/displacement cycle was repeated until the desired oligomer was obtained.

10 Cleavage of the resin from the polycationic agent is as follows. The dried resin was placed in a glass scintillation vial containing a teflon-coated micro stir bar, and approximately 5 ml of 95% trifluoroacetic acid (TFA) in water was added. The solution was stirred for 20 minutes and then filtered through an 8-ml solid-phase extraction (SPE) column fitted with a 20- μ m polyethylene frit into a 50 ml polypropylene conical centrifuge tube.

15 The resin was washed with 1 ml 95% TFA. The combined filtrates were then lyophilized three times from 1:1 acetonitrile:water. Material was redissolved to a concentration of 5 mM in 5% acetonitrile in water.

Preparation of guanidinoalkyl- containing Polymers:

20 The guanidinoalkyl sidechains were introduced into the polymers by post-synthesis modification of aminoalkyl sidechains. Thus, polymers were synthesized by the submonomer method as described above except that methoxybenzhydrylamine (MBHA) resin was used instead of the Rink resin. Wherever a guanidinoalky sidechain was desired, a mono-Boc-alkanediamine was incorporated in the displacement step. After elaboration of the polymers, the 25 sidechain Boc groups were removed by treatment with 95% TFA/water for 20 min at room temp. (This does not remove the oligomer from the solid support). The free amino groups were then guanidinylated by treatment with 1 H-pyrazole-1-carboxamidine (1 M in DMF, 2 x 1 hr, 40°C). After washing with DMF and methylene chloride, the oligomer was cleaved from the resin with hydrofluoric acid, and lyophilized.

Preparation of folic acid - polymer conjugates:

Folic acid - polymer conjugates were prepared by adding a linker to the N-terminus of the resin-bound polymer which was then acylated with folic acid. Specifically, after elaboration of the polymer, the N-terminus was acylated with Fmoc-aminohexanoic acid (0.5 M in DMF, 0.5 M hydroxybenzotriazole, 0.5 M diisopropylcarbodiimide (DIC), 1 x 1 hr, room temp.). After Fmoc group removal (20% piperidine/DMF, 1 x 20 min, room temp.), the free primary amino group was acylated with folic acid (0.1 M in DMSO, 0.1 M DIC, 1 x 2 hr, 50°C). After washing of the resin, the conjugate was cleaved with 95% TFA/water in the usual fashion.

10

Example 2Condensation of Polynucleotides

Polycationic agents were synthesized and isolated to a final concentration of 5 mM as described in Example 1. Polynucleotides were condensed with RZ110, RZ112, and RZ120 series compounds according to the following procedure.

- (1) Dilute all polycationic agents to a final concentration of 3 nanomoles of positive charge per microliter.
- (2) Add 1 µg of DNA to 1-2µl of diluted polycationic agents.
- (3) Adjust volume to 10 µl. This mixture can be stored overnight at 20 4°C.
- (4) Add of 5 µl of DNA/polycationic mixture to 2 µl of 5X buffer, which does not contain SDS to maintain the complex. (5X buffer = 40% sucrose, 0.25% bromphenol blue and 200 mM Tris Acetate, 4 mM EDTA (PH 7.8).
- (5) Adjust volume to 10 µl.
- (6) Run sample on a 1% agarose gel utilizing 75 volts for 1.5 hours..

Between 1 to 2 µl, all polycationic agents were judged to retard the migration of DNA into an agarose gel.

Example 3Inhibition of Serum Degradation

The RZ110, RZ112, and RZ120 series compounds were mixed with polynucleotide as described in Example 2. Five microliters of the overnight mixture was added to 5 µl of BalbC mouse serum. The serum was not heat treated but freeze thawed. The serum, polycationic agent, and polynucleotide mixture was incubated typically for 30 minutes at 37°C. The time of incubation varied between 5 and 60 minutes

5 Next, 2 µl of 5X buffer containing 0.5% (wt/v) SDS was added to the
incubated mixture. This final solution was loaded onto a 1% agarose gel and
10 electrophoresed at 75 volts for 1.5 hours.

All of the compounds tested, i.e., the entire RZ110, 112, and 120 series, provided significant protection in a direct comparison. The entire RZ112 series and RZ110-3 and RZ110-8 inhibited serum degradation better than poly-L-lysine.

15

Example 4Peptoid Mediated *In Vitro* Delivery

DNA comprising a luciferase gene 1µg/µl, was diluted into endotoxin free water. The plasmid DNA was CMVKm luciferase, which is described in more detail in Example 5.

20 The transfection protocol for *in vitro* delivery was as follows:

(A) HT1080 cells were used. These cells are available from American Type Culture Collection, Rockville, Maryland, USA, Accession No. CCL 121. This is a fibrosarcoma. The growth medium was Dulbecco's Modified Eagle medium (DME) with 10% heat-inactivated fetal calf serum.

25 (B) Twenty four hours prior to transfection, the cells were placed at 5 X 10⁴ per well of a 24-well plate in 1 ml of medium.

1. Feed cells with 500µl of DME-10% fetal calf serum (FCS) or 500µl Opti-MEM®. Opti-Mem® can be purchased from Gibco BRL, Life Technologies, Inc., Gaithersburg, Maryland, USA.

30 2. Add 200 µl Opti-MEM® to each tube.

3. Add 3 μ l of the desired polycationic agent to the 200 μ l of Opti-MEM®.
4. Add 2 μ l of 1 μ g/ μ l luciferase DNA, mix.
5. Incubate mixture for 5 minutes at room temperature.
6. Add 100 μ l of the polycationic agent/DNA mixture to plate with DME-FCS, 100 μ l to cells fed with Opti-MEM®.
7. Incubate cells and polycationic agent/DNA mixture for ~4 hours at 37°C.
8. Change media on all cells to DME-FCS.
9. DME-FCS was used as a positive control.

As a control, a transfectant, LT1, was used from Panvera, Inc., Madison, Wisconsin, USA to transfect cells in serum and cells in Opti-MEM®.

10. Cells were tested for luciferase activity using a Promega Luciferase Assay System from Promega, Madison, Wisconsin, USA., in accordance with the manufacturer's directions.

Example 5
Targeting Ligand

A. Cells, Vector, and Compositions Used.

In a first experiment, murine endothelial cells (Py-4-1) which express
5 high levels of acetylated-LDL receptors. The cells and the LDL receptors are
described in Dubois *et al.*, 1991, *Exp. Cell Res.* **196**:302-313.

A luciferase-containing plasmid (pCMVkmLUC) was used to determine
if polynucleotides could be delivered and expressed into endothelial cells when
associated with polycationic agents described in Example 1 with acetylated-LDL
10 (Ac-LDL). A description of the identification and isolation of endothelial cells
based on their increased uptake of acetylated-low density lipoprotein is in Voyta
et al., 1984, *J. Cell Biol.* **99**: 2034-2040.

The plasmid used in these experiments pCMVkmLUC, was constructed
by inserting the luc + gene from pSP-luc+ (Promega Corporation, Madison, WI)
15 into the expression vector pCMVkm2. Briefly, pSP-luc+ was digested with the
restriction enzymes Nhe1-EcoRV (Boehringer Mannheim, Indianapolis, IN) and
a fragment of 1691 bp was isolated by standard methods. This fragment was
inserted into pCMVkm2, which had been digested with XbaI and EcoRV using
the Rapid Ligation Kit (Boehringer Mannheim, Indianapolis, IN). The sequence
20 of pCMVkm2 is depicted in SEQ ID NO:2 and described below. The luc + gene
was cloned into pCMVkm2 such that expression is driven by the CMV
immediate early enhancer promoter and terminated by the bovine growth
hormone polyadenylation signal.

The luciferase expression was compared to levels obtained with the same
25 vector delivered in conjunction with lipofectamine, an agent used commonly to
transfect cells *in vitro* (Hawley-Nelson *et al.*, 1993, *Focus* **15**:73). The results are
presented in the table below.

B. Method of Transfection:

Briefly, the cells were plated in 24 well dishes, grown to approximately
30 80% confluence, transfected and assayed 24 hours later for luciferase activity.
All transfections were done in serum containing medium. During transfection
mixture preparation, pCMVkmLUC was first mixed with RZ 112, and the DNA-

cationic polycationic agent complexes were then added to Ac-LDL. Serum containing medium was then added to the mixtures to adjust the volume delivered to each well to 0.5 ml.

Lipofectamine was used as a positive control. No lipoprotein was added 5 to this positive control. Lipofectamine is a 3:1 (w/w) liposome formulation of the polycationic lipid 2,3,-dioleylosy-N-[2(spermine-carboxamido)ethyl]-N,N-dimethyl-1-propanaminiumtrifluoroacetate (DOSPA) and the neutral lipid dioleoyl phosphatidyl-ethanolamine (DOPE) in membrane-filtered water. Lipofectamine can be purchased from Life Technologies, Gaithersburg, 10 Maryland, USA).

C. Luciferase Assay

Luciferase activity was assayed using the Promega Luciferase Assay System, Madison, Wisconsin.

15 D. Results

Table 1 shows the results of an experiment where the polycationic agent, RZ-112-2 was compared to lipofectamine to deliver the luciferase gene to cells comprising the acetylated LDL receptor.

Table 1
Luciferase Activity

| Group | Ac-LDL (μ g) | pCMVkmLUC (μ g) | RZ 112-2 (nm) | pg luc/mg protein |

Example 6Comparison of Cells with and without Acetylated LDL ReceptorsA. Cells with Acetylated LDL Receptors

- For this experiment, K1735 mouse, epithelial melanoma cells were used.
- 5 These cells express low or non-existent levels of Ac-LDL receptors. A description of the cells is in J. Natl. Cancer Inst. 69(4): (1982).

B. Methods

- Briefly, the cells were plated in 24 well dishes at 10,000 cells per well in
- 10 DME with 10% FCS supplemented with 2 mM L-glutamine. The Py-4-1 cells were cultured in 10% CO₂ at 37°C. The K1735 cells were cultured in 5% CO₂ at 37°C. The cells were grown to approximately 50% confluence, transfected and assayed 24 hours later for luciferase activity. All transfections were done in serum containing medium.
- 15 During transfection mixture preparation, pCMVkmLUC was first mixed with RZ 112-2, and the DNA-polycationic agent complexes were then added to Ac-LDL. Serum containing medium was then added to the mixtures to adjust the volume delivered to each well to 0.5 ml.

Example 7
Injection of Polynucleotides Encoding Erythropoietin

A. Polynucleotides

CMVkm2 is the standard vector used in these studies. CMVkm2 is a vector optimized for expression in mammalian cells. The gene of interest is 5 cloned into a polylinker which is inserted 3' of a human CMV expression cassette. This cassette contains the human CMV immediate early promoter/enhancer followed by intron A of the human CMV immediate early region (Chapman *et al.*, 1991, *Nucl. Acids Res.* 19:3937-3986). Transcription is terminated by a polyadenylation site from the bovine growth hormone gene, 10 which has been cloned immediately 3' of the polylinker. See SEQ ID NO:2 for the CMVkm2 vector.

The CMV-km-cmEPO vector was constructed from CMVkm2 as follows. The cynomolgus monkey EPO cDNA was acquired from the ATCC (Accession No. 67545, Rockville, MD). This plasmid was cut with AvrII and 15 BglII and inserted into the XbaI and BamHI sites of the CMVkm2 vector. The inserted sequence contains the entire coding region of cmEPO (Genbank accession M18189). See SEQ ID NO:3.

B. Mice

Immunodeficient severe combined immunodeficiency (SCID) mice were 20 obtained from Charles River Labs, Wilmington, Massachusetts, USA.

Intramuscular injections were performed as follows: mice were anaesthetized with 50 µl of a solution which contained 80 mg/ml ketamine and 4 mg/ml of xylazine. The area surrounding the anterior tibialis muscle was shaved. Fifty µl of DNA, at a concentration of 2.7 ug/µl in .9% saline solution was 25 injected into the anterior tibialis muscle of both legs using a 28 gauge needle. Twenty-four hours after the first injection, a second injection was performed using the identical protocol. Blood was taken from the orbital sinus to determine hematocrits on a weekly basis.

C. Result

The hematocrit readings on 6 mice which were injected with plasmid, CMVkm-crnEpo (which expresses the cynomolgus monkeys EPO cDNA), are shown in Table 3 below. The row marked control shows the average reading for 5 three uninjected mice. The raw data for the three control mice is shown in the lower part of Table 3. Mouse 2 in the injected group died between 4 and 5 weeks post-injection.

Example 8Injection of Polynucleotides Encoding LeptinA. Polynucleotides

5 The CMV-km2 vector, described above, was used for these experiments. Either the wild-type or HA version of the leptin coding region was inserted into the vector. The map of the plasmid is depicted in Figure 4 and the sequence of the vector with the wild type leptin is shown in SEQ ID NO:4.

B. Mice

10 Ob/ob mice were obtained from Jackson Labs, Bar Harbor, Maine, USA. The first of the recessive obesity mutations, the *obese* mutation (*ob*) was identified and described in 1950 by Ingall *et al.*, 1950, *J. Hered.* 41:317-318. Subsequently, 5 single-gene mutations in mice have been observed to produce an obese phenotype, as described in Friedman *et al.*, 1990, *Cell* 69:217-220. (More recently, the mouse *obese* gene and its human homologue have been 15 cloned, as described in Zhang *et al.*, 1994, *Nature* 372:425).

C. Method

Intramuscular injections were performed as follows: mice were anaesthetized with the same ketamine solution described above in the Example 7 and the area surrounding the anterior tibialis muscle was shaved.

20 Fifty microliters of DNA at a concentration of 3.3. $\mu\text{g}/\mu\text{l}$ in 0.9% saline solution was injected into the anterior tibialis muscle of both legs using a 28 gauge needle.

Seventy-two hours after the first injection, a second injection was performed using the identical protocol.

25 Group 1 ob/ob mice were injected with a plasmid (CMVkm leptin-wt) which encodes the wild-type mouse leptin protein.

Group 2 ob/ob mice were injected with a plasmid (CMVkm-leptinHA) which encodes a form of mouse leptin which is modified with the epitope which is recognized by the antibody 12CA5. The amino acid sequence of the epitope is SYPYDVPDYASLGGPS (Wilson *et al.*, 1984, *Cell* 37: 767-778).

30 Group 3 ob/ob mice were injected with a solution of 0.9% saline.

The mice were weighed each day (see Table 4) and the proportional weight gain for each mouse during the first eight days was calculated. The results are shown in Table 5. For any given day, the weight was subtracted from the weight of the individual mouse on day 0, 5 and the difference was divided by the weight on day 0. The proportional weight change data from day 8 was analyzed using an unpaired t-test. When compared with group 3 control mice the p value from group 2 mice was 0.004. When compared with group 3 control mice, the p value for group 1 mice is 0.0038.

Note: the mice were not weighed on day 1 and day 2, the values for these days were
10 extrapolated from day 3.

Example 9Peptoid Mediated *In Vitro* Delivery in COS, HT1080, and 293 Cell Lines

COS cells (available from the American Type Culture Collection, Rockville, MD, under Accession No. CRL 1651 and HT1080 cells (available from the American Type Culture Collection, Rockville, MD, under Accession No. CCL 121) were cultured and 5 transfected with pCMVkmLUC and various polycationic agents of the present invention (described in Example 1) according to the transfection protocol described in Example 4. Luciferase activity was assayed according to the method described in Example 4. Total cell protein was measured using a Pierce BCA kit according to manufacturer's directions.

The results, shown in Figure 7A, indicate that the ability of the polycationic agents to 10 mediate transfection is not dependent on cell line type. Polycationic agents having a repeating trimer motif of neutral and cationic sidechains were particularly effective at mediating transfection.

Transfection efficiencies for a homologous series of cationic peptoids were evaluated. Specifically, cationic peptoids RZ-110-1 (18-mer), RZ-120-3 (24mer), RZ120-7 (36mer), and 15 RZ120-11 (48mer), which have the same repeating (HHP) motif were evaluated for their ability to transfect COS and HT1080 cells. These polycationic agents were complexed with pCMVkmLUC at a 2:1, + to - charge ratio. The concentration of negative charges on DNA was calculated using 3.03 nmol of phosphate per 1 µg of DNA, on the basis of the average molecular weight of 330 for each nucleotide. The formula weight of the polycationic agent 20 was calculated as a semi-trifluoroacetate salt (50% of amino groups form salt with TFA), and the concentration of the polycationic agent was determined on the basis of the weight of the lyophilized peptoid. Amino groups were formally considered to be fully protonated to obtain the number of positive charges on the polycationic agent interest when calculating the + to - charge.

As shown in Figure 7B, transfection efficiencies for this particular series of cationic peptoids were largely independent of oligomer length for peptoids having 24 or more 25 monomeric units.

Transfection efficiencies using polycationic agent RZ145-1 and commercially available cationic lipids, DMRIE-C™, Lipofectin® and lipofectamine were evaluated. In these 30 experiments RZ145-1 was complexed with pCMVkmLUC at a 2:1, + to - charge ratio. Transfection with DMRIE-C™ Lipofectin®, lipofectamine was conducted according to

manufacturer's directions. The cationic lipids were also employed at a 2:1, + to - charge ratio. 293 human embryonic kidney cells (Microbix, Toronto, Ontario, Canada), HT1080 cells, and NIH-3T3 cells (available from the American Type Culture Collection, Rockville, MD, Accession No. CRL 1658) were transfected, cultured either in the presence or absence of 10% serum, then assayed for luciferase production using the same protocol as described in Example 4. Luciferase was measured, as described in Example 4, 48 hours after initial transfection. Total cell protein was measured using a Pierce BCA kit according to manufacturer's directions.

- The results, shown in Figure 8, indicate that, in contrast to Lipofectin® and 10 lipofectamine, which were respectively 10- and 100-fold less efficient in the presence of serum, gene transfer mediated by polycationic agent RZ145-1 was insensitive to the presence of serum.

Transfection mediated by polycationic polymers, such as polylysine and histones, is greatly enhanced by addition of chloroquine to the transfection media. To determine whether 15 chloroquine affected transfection mediated by polycationic agents of the present invention, HT1080 and 293 cells were transfected using RZ145-1 in the presence and absence of chloroquine. As a control, the same cell lines were transfected with polylysine both in the presence and absence of chloroquine. The results, shown in Figure 9, indicate that the polycationic agent RZ145-1 was equally effective at mediating transfection both with and 20 without chloroquine. In contrast, polylysine-mediated transfection in the absence of chloroquine was 100-fold lower than polylysine mediated transfection in the presence of chloroquine. In addition, the results indicate that cationic peptoid mediated transfection is more efficient than polylysine mediated transfection.

Example 10

Preparation of a Stable Formulation of DNA/Polycationic Agent Complex

A. DNA/Polycatonic Agent Complex Formation (2:1, + to - Charge Ratio)

All operations were carried out at ambient temperature. DGPW (diagnosis grade purified water) was used to prepare the stock solutions. Both the pycatonic agent and DNA samples had low salt concentrations (i.e., < 1mM) to avoid precipitation.

5 (1) Batch Method

Complexes of polycationic agent RZ145-1 and pCMVkmLUC, as follows, for up to 250 µg DNA. DNA (i.e., pCMVkmLUC) was diluted with 30% (v/v) ethanol in water to a concentration of 50 µg/ml corresponding to 151 µM of negative charge. RZ145-1 was diluted to 23.2 µM in 30% ethanol in water. To 1 part of the polycationic agent solution was added 1 part of DNA solution as quickly as possible with gentle agitation. The DNA solution was added to the solution of polycationic agent (rather than vice-versa) to avoid precipitation. Slow addition of the two solutions was avoided to avoid precipitation and the formation of large complexes.

10 (2) Continuous Method

For more than 250 µg of DNA, a continuous method for preparing concentrated formulations of polycationic agent/DNA complex is preferred. The DNA and peptoid solutions were prepared as above and placed into separate bottles. Each bottle was connected to one port of a mixing tee. The bottles were simultaneously pressurized with 2 to 3 psi to deliver the two streams to the mixing tee at the same flow rate (e.g., 20 ml/min or higher).

B. Concentration Step

Two milliliters of the DNA-polycationic agent complex from part A was placed in a Centricon®-100 (Amico Inc. Beverly, MA), and centrifuged at 1000 x g for 30 minutes or until the volume of the retentate containing polycationic agentDNA complex was approximately 50 µl. The filtrate was removed from the bottom receiver. The retentate was diluted with 2 ml of 5% glucose, and concentrated to 50 µl again. This operation was repeated again to produce a concentrated complex solution containing 1 mg/ml DNA in 5% glucose. This concentration step can be conducted at either 4°C or at ambient temperature. The ethanol content of the final concentrated solution was less than 0.1%. No precipitation was observed in the concentrated solution.

SEQUENCE LISTING

(1) GENERAL INFORMATION:

(i) APPLICANT: Zuckermann *et al.*(ii) TITLE OF INVENTION: Compositions and Methods for
Polynucleotide Delivery

(iii) NUMBER OF SEQUENCES: 4

(iv) CORRESPONDENCE ADDRESS:

- (A) ADDRESSEE: Chiron Corporation
- (B) STREET: 4560 Horton Street
- (C) CITY: Emeryville
- (D) STATE: California
- (E) COUNTRY: U.S.A.
- (F) ZIP: 94608-2916

(v) COMPUTER READABLE FORM:

- (A) MEDIUM TYPE: Floppy disk
- (B) COMPUTER: IBM PC compatible
- (C) OPERATING SYSTEM: PC-DOS/MS-DOS
- (D) SOFTWARE: PatentIn Release #1.0, Version #1.30

(vi) CURRENT APPLICATION DATA:

- (A) APPLICATION NUMBER:
- (B) FILING DATE:
- (C) CLASSIFICATION:

(viii) ATTORNEY/AGENT INFORMATION:

- (A) NAME: Fujita, Sharon M.
- (B) REGISTRATION NUMBER: 38,459
- (C) REFERENCE/DOCKET NUMBER: 1218.002

(ix) TELECOMMUNICATION INFORMATION:

- (A) TELEPHONE: (510) 923-2706
- (B) TELEFAX: (510) 655-3542

(2) INFORMATION FOR SEQ ID NO:1:

(i) SEQUENCE CHARACTERISTICS:

- (A) LENGTH: 9600 base pairs
- (B) TYPE: nucleic acid
- (C) STRANDEDNESS: single
- (D) TOPOLOGY: linear

(ii) MOLECULE TYPE: DNA (genomic)

WHAT IS CLAIMED:

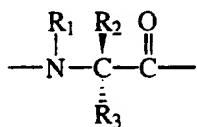

1. A polycationic agent having the following formula:

wherein

n is an integer from 10 to 100;

R_1 , R_2 , and R_3 for each monomer,

are independently selected from moieties having a molecular weight from 1 to 200 daltons;

T_a and T_c are terminating groups;

R_1 is not hydrogen for at least one monomer;

wherein said polycationic agent comprises at least 25% positively charged monomers, excluding the terminal groups, and

wherein said polycationic agent exhibits a net positive electrical charge at a physiological pH.

2. The polycationic agent according to claim 1, wherein said polycationic agent comprises repeating trimers.

3. The polycationic agent according to claim 2, wherein two R₁ groups in each trimer are neutral moieties and one R₁ group in each trimer is a cationic moiety.

4. The polycationic agent according to claim 1, wherein R₁ is selected from the group consisting of positively charged, negatively charged and neutral moieties.

5. The polycationic agent according to claim 1, wherein R₁ is selected from substituents found on amino acids.

6. The polycationic agent of claim 1, wherein R₁ is selected from the group consisting of aromatic and aliphatic groups.

7. The polycationic agent according to claim 1, wherein at least one R₁ is selected from the group consisting of alkylammonium, aminoalkyl, guanidinoalkyl, amidinoalkyl, aminocyclohexyl, piperidyl, guanidinobenzyl, amidinobenzyl, pyridylmethyl, aminobenzyl, alkyphenyl, indolylalkyl, alkoxyphenylalkyl, halophenylalkyl, and hydroxyphenylalkyl.

8. The polycationic agent according to claim 3, wherein said cationic moiety is aminoethyl.

9. The polycationic agent according to claim 8, wherein said neutral moieties are selected from the group consisting of phenethyl, benzyl, phenylpropyl, (R) alpha-methylbenzyl, (S) alpha-methylbenzyl, methoxyphenethyl, and chlorophenethyl.

10. The polycationic agent of claim 1, wherein R₁ and R₂ are both hydrogen for at least one monomer.

11. The polycationic agent of claim 10 wherein n is 36.

12. The polycationic agent of claim 10, wherein n is 24.

13. The polycationic agent of claim 10, wherein n is 18.

14. The polycationic agent of claim 10, wherein n is 12.

15. The polycationic agent of claim 8, wherein Ta and Tc are terminal groups selected from the group consisting of polypeptide, lipid, lipoprotein, vitamin, hormone, polyakylene glycol, and saccharide.

16. A composition comprising:

- (i) a polynucleotide; and
- (ii) the polycationic agent of claim 1, wherein said polycationic agent is capable of mediating entry of polynucleotides into a cell.

17. A pharmaceutical composition comprising:

- (i) a pharmaceutically acceptable carrier;
- (ii) a therapeutically effective amount of polynucleotides; and
- (iii) an amount effective to neutralize said polynucleotides of the polycationic agent of claim 1 wherein said polycationic agent is capable of mediating entry of polynucleotides into a cell.

18. A method of complexing polynucleotides with a polycationic agent comprising:

- (i) providing a polynucleotide; and
- (ii) contacting said polynucleotide with the polycationic agent of claim 1, wherein said polycationic agent is capable of mediating entry of polynucleotides into a cell.

19. A method of condensing polynucleotides, said method comprising: contacting a polynucleotide with a condensing amount of the polycationic agent of claim 1, wherein said condensing amount is an amount of polycationic agent sufficient to reduce the size of said polynucleotide.

20. A method of inhibiting serum degradation of polynucleotides, said method comprising contacting a polynucleotide with the polycationic agent of claim 1 wherein said polycationic agent is present in an amount effective to inhibit serum degradation by at least 10 minutes.

21. A composition comprising:

- (i) a lipoprotein;
- (ii) a polynucleotide binding molecule; and
- (iii) a polynucleotide,

wherein said composition is capable of increasing the frequency of polynucleotide uptake into a cell.

22. The composition of claim 21, wherein the lipoprotein is selected from the group consisting of high density lipoprotein, intermediate density lipoprotein, low density lipoprotein, and very low density lipoprotein.

23. The composition of claim 21, wherein the lipoprotein is a mutant, fragment or fusion of the protein selected from the group consisting of high density lipoprotein, intermediate density lipoprotein, low density lipoprotein, and very low density lipoprotein.

24. The composition of claim 21, wherein the lipoprotein is acetylated low density lipoprotein.

25. A pharmaceutical composition comprising
(a) a therapeutically effective amount of a polynucleotide;
(b) a polynucleotide binding molecule in an amount effective to neutralize the negative charge of said polynucleotide; and
(c) a therapeutically effective amount of lipoprotein.

26. The pharmaceutical composition of claim 25, wherein said polynucleotide is a polycationic agent.

27. A method of producing a composition for facilitating entry of a polynucleotide into a cell said method comprising:
(i) providing a polynucleotide
(ii) providing a polynucleotide binding molecule in an amount effective to neutralize said polynucleotide;
(ii) contacting said polynucleotide with said polynucleotide binding molecule to form a complex;
(iii) providing a lipoprotein; then
(iv) contacting the complex with said lipoprotein.

28. A method of increasing the frequency of polynucleotide uptake into a cell said method comprising

- (i) providing a composition that comprises
 - (a) a therapeutically effective amount of a polynucleotide;
 - (b) a polynucleotide binding molecule in an amount effective to neutralize said polynucleotide; and
 - (c) an effective amount lipoprotein; then
- (ii) contacting said composition to said cell.

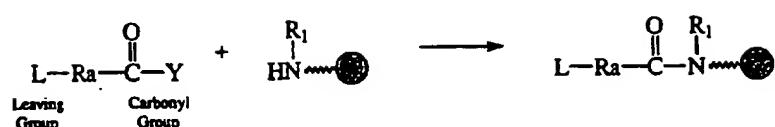

29. A method of increasing the frequency of polynucleotide uptake into a cell said method comprising:

- (i) providing a composition that comprises
 - (a) a polynucleotide; and
 - (b) the polycationic agent of claim 1 in an amount effective to neutralize the negative charge of said polynucleotide; then
- (ii) contacting said composition to said cell.
